Entered, according to Act of Congress, in the year 1886, by
GINN & COMPANY,
in the Office of the Librarian of Congress, at Washington.

PREFACE.

THIS book is almost entirely made up of lecture-notes which from time to time during the last four years I have written out for the use of students who have begun with me the study of what I have ventured to call, after Neumann, the Newtonian Potential Function.

The notes were intended for readers somewhat familiar with the principles of the Differential and Integral Calculus, but unacquainted with many of the methods commonly used in applying Mathematics to the study of physical problems. These students, I learned, found it difficult to get from any single book in English a treatment of the subject at once elementary enough to be within their easy comprehension, and at the same time suited to the purposes of such of them as intended eventually to pursue the subject farther, or wished, without necessarily making a specialty of Mathematical Physics, to prepare themselves to study Experimental Physics thoroughly and understandingly. What is here printed seems to have been of use to some of those who have read it in manuscript, and it is hoped that it may now be helpful to a larger number of students.

Since these notes are professedly elementary in character, I feel that no apology is needed for what may seem to be the rather prolix way in which some of the subjects are treated, or for an arrangement of matter which would be

unsuitable in a book intended for a different class of readers. I have not hesitated to use a long proof whenever this has seemed to me more easily comprehensible than a short and mathematically neater one, and I have often given more than one demonstration of a single theorem in order to illustrate different methods of work. Although I have used freely the notation* of the Calculus, I have assumed on the part of the reader only an elementary knowledge of its principles.

The short treatment of Electrostatics and Electrokinematics in Chapter v. is introduced to show how the theorems of the preceding chapters may be made useful in discussing a certain class of physical problems; but it is hoped that a person who has mastered even the very little here given will be able, with the aid of a good treatise on Descriptive Physics, to understand some Electric phenomena which often puzzle those who have studied the subject from the experimental side only. It is also hoped that those readers who mean to study Electricity from

* In this book the change made in a function u by giving to the independent variable x the arbitrary, finite increment Δx , and keeping the other independent variables, if there are any, unchanged, is denoted by $\Delta_x u$. Similarly, $\Delta_y u$ and $\Delta_z u$ express the increments of u due to changes respectively in y alone and in z alone. The total change in u due to simultaneous changes in all the independent variables is sometimes denoted by Δu ; so that if $u = f(x, y, z)$,

$$\Delta u = \frac{\Delta_x u}{\Delta x} \cdot \Delta x + \frac{\Delta_y u}{\Delta y} \cdot \Delta y + \frac{\Delta_z u}{\Delta z} \cdot \Delta z + \epsilon,$$

where ϵ is an infinitesimal of an order higher than the first.

The partial derivatives of u with respect to x , y , and z are denoted by $D_x u$, $D_y u$, and $D_z u$, and the sign \doteq placed between a variable and a constant is used to show that the former is to be made to approach the latter as its limit. In those cases where it is desirable to draw attention to the fact that a certain derivative is total, the differential notation $\frac{du}{dx}$ is used.

the mathematical point of view will find what they have learned here useful when they take up standard works on the subject.

My sincere thanks are due to H. N. Wheeler, A.M., who has read much of the manuscript of the following pages and all of the proof, and to Dr. E. H. Hall, who has examined parts of Chapters iv. and v. and helped me with various suggestions. I am indebted to other friends also, and among them to Mr. W. A. Stone for the use of some of his problems.

The reader who wishes to get a thorough knowledge of the properties of the Newtonian Potential Function and of its applications to problems in Electricity is referred to the following works, which, with others, I have consulted and used in writing these notes.

Betti: Teorica delle Forze Newtoniane e sue Applicazioni all' Elettrostatica e al Magnetismo.

Clausius: Die Potentialfunction und das Potential.

Cumming: An Introduction to the Theory of Electricity.

Chrystal: The article "Electricity" in the Ninth Edition of the Encyclopædia Britannica.

Dirichlet: Vorlesungen über die im umgekehrten Verhältniss des Quadrats der Entfernung wirkenden Kräfte.

Gauss: Allgemeine Lehrsätze in Beziehung auf die im verkehrten Verhältnisse des Quadrates der Entfernung wirkenden Anziehungs- und Abstossungskräfte. Also other papers to be found in Volume V. of his Gesammelte Werke.

Green: An Essay on the Application of Mathematical Analysis to the Theories of Electricity and Magnetism.*

Mascart: Traité d'Electricité Statique. Also Wallentin's translation of the same work into German, with additions.

* A copy of the original edition of this paper is to be found in the Library of Harvard University, Gore Hall, Cambridge. The paper has been reprinted by Ferrers in "The Mathematical Papers of George Green," and by Thomson in Crelle's Journal.

- Mascart et Joubert:** Leçons sur l'Electricité et le Magnetisme.
Also Atkinson's translation of the same work into English, with additions.
- Mathieu:** Théorie du Potential et ses Applications à l'Electrostatique et au Magnétisme.
- Maxwell:** An Elementary Treatise on Electricity. A Treatise on Electricity and Magnetism.
- Minchin:** A Treatise on Statics.*
- C. Neumann:** Untersuchungen über das Logarithmische und Newton'sche Potential.
- Riemann:** Schwere, Electricität und Magnetismus, edited by Hattendorff.
- Schell:** Theorie der Bewegung und der Kräfte.
- Thomson:** Reprint of Papers on Electrostatics and Magnetism.
- Thomson and Tait:** A Treatise on Natural Philosophy.
- Todhunter:** A Treatise on Analytical Statics. A History of the Mathematical Theories of Attraction and the Figure of the Earth.
- Watson and Burbury:** The Mathematical Theory of Electricity and Magnetism.
- Wiedemann:** Die Lehre von der Electricität.

* The third edition of Minchin's Statics with its admirable treatment of the subjects here discussed did not reach me, unfortunately, until all but a very few of the following pages were electrotyped.

TABLE OF CONTENTS.

CHAPTER I.

THE ATTRACTION OF GRAVITATION.

SECTION.	PAGE
1. The law of gravitation	1
2. The attraction at a point	1
3. The unit of force	2
4. The attraction due to discrete particles	2
5. The attraction of a straight wire at a point in its axis	3
6. The attraction at any point due to a straight wire	4
7. The attraction at a point in its axis due to a cylinder of revolution	7
8. The attraction at the vertex of a cone of revolution due to the whole cone and to different frusta	8
9. The attraction due to a homogeneous spherical shell; to a solid sphere	11
10. The attraction due to a homogeneous hemisphere	13
11. Apparent anomalies in the latitudes of places near the foot of a hemispherical hill	15
12. The attraction due to any ellipsoidal homœoid is zero at all points within the cavity enclosed by the shell	16
13. The attraction due to a spherical shell whose density at any point depends upon the distance of the point from the centre	18
14. The attraction at any point due to any given mass	19
15. The component in any direction of the attraction at a point P due to a given mass is always finite	21

SECTION	PAGE
16. The attraction between two straight wires	22
17. The attraction between two spheres	23
18. The attraction between any two rigid bodies	24

CHAPTER II.

THE NEWTONIAN POTENTIAL FUNCTION IN THE CASE OF GRAVITATION.

19. Definition of the potential function	29
20. The derivatives of the potential function relative to the space coördinates are functions of these coördinates which represent the components parallel to the coördinate axes of the attraction at the point (x, y, z)	30
21. Extension of the statement of the last section	31
22. The potential function due to a given attracting mass is everywhere finite, and the statements of the two preceding sections hold good for points within the attracting mass	32
23. The potential function due to a straight wire	34
24. The potential function due to a spherical shell	35
25. Equipotential surfaces and their properties	37
26. The potential function is zero at infinity	40
27. The potential function as a measure of work	40
28. Laplace's Equation	42
29. The second derivatives of the potential function are finite at points within the attracting mass	43
30. The first derivatives of the potential function change continuously as the point (x, y, z) moves through the boundaries of an attracting mass	48
31. Theorem due to Gauss. The potential function can have no maxima or minima at points of empty space	50
32. Tubes of force and their properties	53
33. Spherical distributions of matter and their attractions	54
34. Cylindrical distributions of matter and their attractions	58

THE
NEWTONIAN POTENTIAL FUNCTION.

CHAPTER I.

THE ATTRACTION OF GRAVITATION.

1. The Law of Gravitation. Every body in the universe attracts every other body with a force which depends for magnitude and direction upon the masses of the two bodies and upon their relative positions.

An *approximate* value of the attraction between any two rigid bodies may be obtained by imagining the bodies to be divided into small particles, and assuming that every particle of the one body attracts every particle of the other with a force directly proportional to the product of the masses of the two particles, and inversely proportional to the square of the distance between their centres or other corresponding points. The *true* value of the attraction is the limit approached by this approximate value as the particles into which the bodies are supposed to be divided are made smaller and smaller.

2. The Attraction at a Point. By “the attraction *at* any point P in space, due to one or more attracting masses,” is meant the limit which would be approached by the value of the attraction on a sphere of unit mass centred at P if the radius of the sphere were made continually smaller and smaller while its mass remained unchanged. The attraction at P is, then, the attraction on a unit mass supposed to be *concentrated* at P .

If the attraction at every point throughout a certain region has a value other than zero, the region is called "a field of force"; and the attraction at any point P in the region is called "the strength of the field" at that point.

3. The Unit of Force. It will presently appear that all spheres made of homogeneous material attract bodies outside of themselves as if the masses of the spheres were concentrated at their middle points. If, then, k be the force of attraction between two unit masses concentrated at points at the unit distance apart, the attraction at a point P due to a homogeneous sphere of radius a and of density ρ is $k \cdot \frac{4\pi a^3 \rho}{3r^2}$, where r is the distance of P from the centre of the sphere. In all that follows, however, we shall take as our *unit of force* the force of attraction between two unit masses concentrated at points at the unit distance apart. Using these units, k in the expression given above becomes 1, and the attraction between two particles of mass m_1 and m_2 concentrated at points r units apart is $\frac{m_1 m_2}{r^2}$.

4. Attraction due to Discrete Particles. The attraction at a point P , due to particles concentrated at different points in the same plane with P , may be expressed in terms of two components at right angles to each other.

FIG. 1.

Let the straight lines joining P with the different particles be denoted by r_1, r_2, r_3, \dots , and the angles which these lines make with some fixed line Px by $\alpha_1, \alpha_2, \alpha_3, \dots$. If, then, the masses

of the several particles are respectively m_1, m_2, m_3, \dots , the components of the attraction at P are

$$X = \frac{m_1 \cos \alpha_1}{r_1^2} + \frac{m_2 \cos \alpha_2}{r_2^2} + \dots = \sum \frac{m \cos \alpha}{r^2} \quad [1]$$

in the direction Px , and

$$Y = \frac{m_1 \sin \alpha_1}{r_1^2} + \frac{m_2 \sin \alpha_2}{r_2^2} + \dots = \sum \frac{m \sin \alpha}{r^2} \quad [2]$$

in the direction Py , perpendicular to Px .

The resultant force at P is

$$R = \sqrt{X^2 + Y^2}, \quad [3]$$

and its line of action makes with Px the angle whose tangent is $\frac{Y}{X}$.

If the particles do not all lie in the same plane with P , we may draw through P three mutually perpendicular axes, and call the angles which the lines joining P with the different particles make with the first axis $\alpha_1, \alpha_2, \alpha_3, \dots$; with the second axis, $\beta_1, \beta_2, \beta_3, \dots$; and with the third axis, $\gamma_1, \gamma_2, \gamma_3, \dots$. The three components in the directions of these axes of the attraction at P due to all the particles are then

$$X = \sum \frac{m \cos \alpha}{r^2}; \quad Y = \sum \frac{m \cos \beta}{r^2}; \quad Z = \sum \frac{m \cos \gamma}{r^2}. \quad [4]$$

The resultant attraction is

$$R = \sqrt{X^2 + Y^2 + Z^2}, \quad [5]$$

and its line of action makes with the axes angles whose cosines are respectively

$$\frac{X}{R}, \quad \frac{Y}{R}, \quad \text{and} \quad \frac{Z}{R}. \quad [6]$$

5. Attraction at a Point in the Produced Axis of a Straight Wire. Let μ be the mass of the unit of length of a uniform straight wire AB of length l , and of cross section so small that

we may suppose the mass of the wire concentrated in its axis (see Fig. 2), and let P be a point in the line AB produced at a

FIG. 2.

distance a from A . Divide the wire into elements of length Δx . The attraction at P due to one of these elements, M , whose nearest point is at a distance x from P , is less than $\frac{\mu\Delta x}{x^2}$ and greater than $\frac{\mu\Delta x}{(x + \Delta x)^2}$.

The attraction at P due to the whole wire lies between $\sum \frac{\mu\Delta x}{x^2}$ and $\sum \frac{\mu\Delta x}{(x + \Delta x)^2}$; but these quantities approach the same limit as Δx is made to approach zero, so that the attraction at P is

$$\lim_{\Delta x \rightarrow 0} \sum \frac{\mu\Delta x}{x^2} = \int_a^{a+l} \frac{\mu dx}{x^2} = \mu \left[\frac{1}{a} - \frac{1}{a+l} \right]. \quad [7]$$

If the coördinates of P , A , and B are respectively $(x, 0, 0)$, $(x_1, 0, 0)$, and $(x_1 + l, 0, 0)$, this result may be put into the form

$$\mu \left[\frac{1}{x_1 - x} - \frac{1}{x_1 - x + l} \right]. \quad [8]$$

6. Attraction at any Point, due to a Straight Wire. Let P (Fig. 3) be any point in the perpendicular drawn to the straight wire AB at A , and let $PA = c$, $AB = l$, $AM = x$, and the angle $ABP = \delta$. Let MN be one of the equal elements of mass ($\mu\Delta x$) into which the wire is divided, and call PM , r . The attraction at P due to this element is approximately equal to $\frac{\mu\Delta x}{r^2}$, and acts in some direction lying between PM and PN . This attraction can be resolved into two components whose approximate values are $\frac{\mu\Delta x \cdot c}{(c^2 + x^2)^{\frac{3}{2}}}$ in the direction PA , and $\frac{\mu\Delta x \cdot x}{(c^2 + x^2)^{\frac{3}{2}}}$ in the

direction PL . The true values of the components in these directions of the attraction at P , due to the whole wire, are, then, respectively :

$$\int_0^l \frac{\mu c dx}{(c^2 + x^2)^{\frac{3}{2}}} = \frac{\mu}{c} \left[\frac{x}{\sqrt{c^2 + x^2}} \right]_0^l = \frac{\mu}{c} \cos \delta, \quad \times \quad [9]$$

and

$$\int_0^l \frac{\mu x dx}{(c^2 + x^2)^{\frac{3}{2}}} = \frac{-\mu}{c} \left[\frac{c}{\sqrt{c^2 + x^2}} \right]_0^l = \frac{\mu}{c} (1 - \sin \delta). \quad \gamma \quad [10]$$

FIG. 3.

The resultant attraction is equal to the square root of the sum of the squares of these components, or

$$R = \frac{\mu}{c} \sqrt{2(1 - \sin \delta)} = \frac{\mu}{c} \sqrt{2(1 - \cos APB)} = \frac{2\mu}{c} \sin \frac{1}{2} APB, \quad [11]$$

and its line of action makes with PA an angle whose tangent is

$$\frac{1 - \sin \delta}{\cos \delta} = \frac{1 - \cos APB}{\sin APB} = \frac{2 \sin^2 \frac{1}{2} APB}{2 \sin \frac{1}{2} APB \cdot \cos \frac{1}{2} APB} = \tan \frac{1}{2} APB.$$

That is, the resultant attraction at P acts in the direction of the bisector of the angle APB .

From these results we can easily obtain the value of the attraction at any point P , due to a uniform straight wire $B'B$ (Fig. 4). Drop a perpendicular PA from P upon the axis of the wire. Let $AB = l$, $AB' = l'$, $PA = c$, $ABP = \delta$, $AB'P = \delta'$, $BPB' = \theta$. The component in the direction PA of the attraction at P is [9]

$$\frac{\mu}{c} (\cos \delta + \cos \delta'),$$

and that in the direction PL is

$$\frac{\mu}{c} (\sin \delta' - \sin \delta),$$

so that the resultant attraction is

$$R = \frac{\mu}{c} \sqrt{2[1 + \cos(\delta + \delta')]} = \frac{2\mu}{c} \cos \frac{1}{2}(\delta + \delta') = \frac{2\mu}{c} \sin \frac{1}{2}\theta. \quad [12]$$

FIG. 4.

The line of action PK of R makes with PA an angle ϕ such that

$$\tan \phi = \frac{\sin \delta' - \sin \delta}{\cos \delta + \cos \delta'} = \tan \frac{1}{2}(\delta' - \delta); \quad [13]$$

$$\therefore B'PK = \frac{\pi}{2} - \delta' + \frac{1}{2}(\delta' - \delta) = \frac{\pi}{2} - \frac{1}{2}(\delta + \delta'),$$

and

$$BPK = \frac{\pi}{2} - \delta - \frac{1}{2}(\delta' - \delta) = \frac{\pi}{2} - \frac{1}{2}(\delta + \delta').$$

It is to be noticed that PK bisects the angle θ , and does not in general pass through the centre of gravity or any other fixed point of the wire. Indeed, the path of a particle moving from rest under the attraction of a straight wire is generally curved; for if the particle should start at a point Q and move a short distance on the bisector of the angle BQB' to Q' , the attraction of the wire would now urge the particle in the direction of the bisector of the angle $BQ'B'$, and this is usually not coincident with the bisector of BQB' .

If q is the area of the cross section of the wire, and ρ the mass of the unit volume of the substance of which the wire is made, we may substitute for μ in the formulæ of this section its value $q\rho$.

If instead of a very thin wire we had a body in the shape of a prism or cylinder of considerable cross section, we might divide this up into a large number of slender prisms and use the equations just obtained to find the limit of the sum of the attractions at any point due to all these elementary prisms. This would be the attraction due to the given body.

7. Attraction at a Point in the Produced Axis of a Cylinder of Revolution. In order to find the attraction due to a homogeneous cylinder of revolution at any point P (Fig. 5) in the axis of the cylinder produced, it will be convenient to imagine the cylinder cut up into discs of constant thickness Δc , by means of planes perpendicular to the axis.

Let ρ be the mass of the unit of volume of the cylinder, and a the radius of its base. Consider a disc whose nearer face is at a distance c from P , and divide it into elements by means of

FIG. 5.

radial planes drawn at angular intervals of $\Delta\theta$ and concentric cylindrical surfaces at radial intervals of Δr .

The mass of any element M whose inner radius is r is equal to $\rho\Delta c \cdot \Delta\theta [r\Delta r + \frac{1}{2}(\Delta r)^2]$, and the whole attraction at P due to M is approximately $\rho \frac{\Delta\theta\Delta c [r\Delta r + \frac{1}{2}(\Delta r)^2]}{c^2 + r^2}$ in a line joining P with some point of M . The component of this attraction in the direction PC is found by multiplying the expression just

area of a $\theta = \pi r^2$; area of a sector = $\frac{1}{2}\theta \cdot r^2$

area of $\square = \frac{1}{2}\Delta\theta \{ (r+\Delta r)^2 - r^2 \}$
 $= \Delta\theta [r\Delta r + \frac{1}{2}(\Delta r)^2]$

given by $\frac{c}{\sqrt{c^2 + r^2}}$, the cosine of the angle CPS , so that the attraction at P in the direction PC , due to the whole disc, is approximately

$$\begin{aligned} \Delta c \cdot \lim \sum \frac{\rho c \Delta \theta [r \Delta r + \frac{1}{2}(\Delta r)^2]}{(c^2 + r^2)^{\frac{3}{2}}} &= \Delta c \int_0^{2\pi} d\theta \int_0^a \frac{\rho c r dr}{(c^2 + r^2)^{\frac{3}{2}}} \\ &= 2\pi\rho \Delta c \left[1 - \frac{c}{\sqrt{c^2 + a^2}} \right]. \end{aligned} \quad [14]$$

If the bases of the cylinder are at distances c_0 and $c_0 + h$ from P , the true value of the attraction at P in the direction PC , due to the cylinder QQ' , is

$$\begin{aligned} \lim_{\Delta c \rightarrow 0} \sum 2\pi\rho \Delta c \left[1 - \frac{c}{\sqrt{c^2 + a^2}} \right] &= 2\pi\rho \int_{c_0}^{c_0+h} \left(1 - \frac{c}{\sqrt{c^2 + a^2}} \right) dc \\ &= 2\pi\rho [h + \sqrt{c_0^2 + a^2} - \sqrt{(c_0 + h)^2 + a^2}]. \end{aligned} \quad [15]$$

This is evidently the whole attraction at P due to the cylinder, for considerations of symmetry show us that the resultant attraction at P has no component perpendicular to PC .

[14] gives the attraction due to the elementary disc $ABA'B'$, on the assumption that the whole matter of the disc is concentrated at the face ABC . The actual attraction at P due to this disc may be found by putting $c_0 = c$ and $h = \Delta c$ in [15].

If a , the radius of the cylinder, is very large compared with h and c_0 , the expression [15] for the attraction at P due to the cylinder approaches the value $2\pi\rho h$.

8. Attraction at the Vertex of a Cone. The attraction due to a homogeneous cone of revolution, at a point at the vertex of the cone, may be found by the aid of [14].

If Fig. 6 represents a plane section of the cone taken through the axis, and if $PM = c$, $MM' = \Delta c$, and $MB = r$, the attraction at P due to the disc $ABCD$ is approximately

$$2\pi\rho \Delta c \left[1 - \frac{c}{\sqrt{c^2 + r^2}} \right] = 2\pi\rho \Delta c (1 - \cos \alpha),$$

and the attraction due to the whole cone is

$$\begin{aligned} \lim_{\Delta c \doteq 0} \sum 2\pi\rho(1 - \cos\alpha)\Delta c &= 2\pi\rho(1 - \cos\alpha) \lim_{\Delta c \doteq 0} \sum \Delta c \\ &= 2\pi\rho(1 - \cos\alpha) \cdot PL. \end{aligned} \quad [16]$$

The attraction at P due to the frustum $ABKN$ is found by subtracting the value of the attraction due to the cone ABP from the expression given in [16]. The result is

$$2\pi\rho(1 - \cos\alpha)(PL - PM) = 2\pi\rho(1 - \cos\alpha)ML, \quad [17]$$

and it is easy to see from this that discs of equal thickness cut out of a cone of revolution at different distances from the vertex by planes perpendicular to the axis exert equal attractions at the vertex of the cone.

FIG. 6.

It follows almost directly that the portions cut out of two concentric spherical shells of equal uniform density and equal thickness, by *any* conical surface having its vertex at the common centre P of the shells, exert equal attraction at this centre; but we may prove this proposition otherwise, as follows:

Divide the inner surface of the portion cut out of one of the shells by the given cone into elements, and make the perimeter of each of these surface elements the directrix of a conical surface having its vertex at P . Divide the given shells into elementary shells of thickness Δr by means of concentric spherical surfaces drawn about P . In this way the attracting masses will be cut up into volume elements.

Let ML' (Fig. 7) represent one of these elements, whose inner surface has a radius equal to r ; then, if the elementary

cone APB intercept an element of area $\Delta\omega$ from a spherical surface of radius unity drawn around P , the area of the surface element at MM' is $r^2\Delta\omega$, and that at LL' is $(r + \Delta r)^2\Delta\omega$. The

FIG. 7.

attraction at P in the direction PM , due to the element ML' , is approximately

$$\rho \frac{r^2 \Delta\omega \Delta r}{r^2} = \rho \Delta\omega \Delta r,$$

and the component of this in any direction Px , making an angle α with PM , is approximately $\rho \Delta\omega \Delta r \cos \alpha$. The attraction at P in the direction Px , due to the whole shell $EDFG$, is, then,

$$X = \lim \sum \rho \Delta r \Delta\omega \cos \alpha,$$

where the sum is to include all the volume elements which go to make up the shell. If $PF = r_0$, $PG = r_1$, $PF' = r_0'$, $PG' = r_1'$, and $\mu = FG = F'G'$,

$$X = \int_{r_0}^{r_1} dr \int \cos \alpha d\omega = \rho \mu \int \cos \alpha d\omega.$$

The attraction at P in the same direction, due to the shell $E'D'F'G'$, is

$$X' = \rho \int_{r_0'}^{r_1'} dr \int \cos \alpha d\omega = \rho \mu \int \cos \alpha d\omega.$$

But the limits of integration with regard to ω are the same in both cases; $\therefore X = X'$, which was to be proved.

If the shells are of different thicknesses, it is evident that they will exert attractions at P proportional to these thicknesses.

The area of the portion which a conical surface cuts out of a spherical surface of unit radius drawn about the vertex of the cone is called "the solid angle" of the conical surface.

9. Attraction of a Spherical Shell. In order to find the attraction at P , any point in space, due to a homogeneous spherical shell of radii r_0 and r_1 , it will be best to begin by dividing up the shell into a large number of concentric shells of thickness Δr , and to consider first the attraction of one of these thin shells, whose inside radius shall be r .

Let ρ be the density of the given shell, that is, the mass of the unit of volume of the material of which the shell is composed. Join P (Fig. 8) with O by a straight line cutting the inner surface of the thin shell at N , and pass a plane through PO cutting this inner surface in a great circle $NLSSL'$, which

FIG. 8.

will serve as a prime meridian. Using N as a pole, describe upon the inner surface of the thin shell a number of parallels of latitude so as to cut off equal arcs on $NLSSL'$. Denote by $\Delta\theta$ the angle which each one of these arcs subtends at O . Through PO pass a number of planes so as to cut up each parallel of latitude into equal arcs. Denote by $\Delta\phi$ the angle between any two contiguous planes of this series. By this means the inner surface of the elementary shell will be divided into small quadrilaterals, each of which will have two sides formed of meridian arcs, of length $r \cdot \Delta\theta$, and two sides formed of arcs of parallels of latitude, of length $r \sin\theta \cdot \Delta\phi$ and $r \sin(\theta + \Delta\theta) \cdot \Delta\phi$, where

θ is the angle which the radius drawn to the parallel of higher latitude makes with ON . The area of one of these quadrilaterals is approximately $r^2 \sin \theta \cdot \Delta \theta \cdot \Delta \phi$, and the thickness of the shell is Δr , so that the element of volume is approximately $r^2 \sin \theta \cdot \Delta r \cdot \Delta \theta \cdot \Delta \phi$. Let $PM = y$, then the attraction at P , due to an element of mass which has a corner at M , is approximately $\frac{\rho r^2 \sin \theta \Delta r \Delta \theta \Delta \phi}{y^2}$, in the direction PM .

This force may be resolved into three components: one in the direction PO , the others in directions perpendicular to PO and to each other; but it is evident from considerations of symmetry that in finding the attraction at P due to the whole shell we shall need only that component which acts in PO . This is approximately $\frac{\rho r^2 \sin \theta \cdot \Delta r \Delta \theta \Delta \phi \cdot \cos KPM}{y^2}$; or, if $PO = c$,

$$\frac{\rho r^2 \sin \theta (c - r \cos \theta) \Delta r \Delta \theta \Delta \phi}{y^3}. \quad [18]$$

The attraction at P due to the whole elementary shell is, then, approximately (truly on the assumption that the whole mass of the shell is concentrated at its inner surface),

$$\Delta r \int \int \frac{\rho r^2 \sin \theta (c - r \cos \theta) d\theta d\phi}{y^3} = \Delta r X; \quad [19]$$

and the true value at P of the attraction due to the given shell is

$$\int_{r_0}^{r_1} X dr. \quad [20]$$

If in the expression for X we substitute for θ its value in terms of y , we have, since

$$y^2 = c^2 + r^2 - 2 cr \cos \theta,$$

and hence $2y dy = 2 cr \sin \theta d\theta$,

$$\begin{aligned} X &= \int_0^{2\pi} d\phi \int_{y_0}^{y_1} \frac{\rho r dy}{2c^2 y^2} (c^2 - r^2 + y^2) = \frac{\pi \rho r}{c^2} \int_{y_0}^{y_1} \left(\frac{c^2 - r^2}{y^2} + 1 \right) dy \\ &= \frac{\pi \rho r}{c^2} \left[\frac{r^2 - c^2 + y^2}{y} \right]_{y_0}^{y_1}. \end{aligned} \quad [21]$$

In order to find the limits of the integration with regard to y , we must distinguish between two cases :

I. If P is a point in the cavity enclosed by the given shell,

$$y_0 = r - c \quad \text{and} \quad y_1 = r + c ;$$

$$\therefore X = \frac{\pi \rho r}{c^2} \left[\frac{r^2 - c^2 + (r + c)^2}{r + c} - \frac{r^2 - c^2 + (r - c)^2}{r - c} \right] = 0, \quad [22]$$

and
$$\int_{r_0}^{r_1} X dr = 0 ; \quad [23]$$

so that a homogeneous spherical shell exerts no attraction at points in the cavity which it encloses.

II. If P is a point without the given shell,

$$y_0 = c - r \quad \text{and} \quad y_1 = c + r ;$$

$$\therefore X = \frac{\pi \rho r}{c^2} \left[\frac{r^2 - c^2 + (c + r)^2}{c + r} - \frac{r^2 - c^2 + (c - r)^2}{c - r} \right] = \frac{4 \pi \rho r^2}{c^2}, \quad [24]$$

and
$$\int_{r_0}^{r_1} X dr = \frac{4}{3} \frac{\pi \rho}{c^2} (r_1^3 - r_0^3). \quad [25]$$

From this it follows that the attraction due to a spherical shell of uniform density is the same, at a point without the shell, as the attraction due to a mass equal to that of the shell concentrated at the shell's centre.

If in [25] we make $r_0 = 0$, we have the attraction, due to a solid sphere of radius r_1 and density ρ , at a point outside the sphere at a distance c from the centre. This is

$$\frac{4 \pi \rho r_1^3}{3 c^2}. \quad [26]$$

10. Attraction due to a Hemisphere. At any point P in the plane of the base of a homogeneous hemisphere, the attraction of the hemisphere gives rise to two components, one directed toward the centre of the base, the other perpendicular to the plane of the base. We will compute the values of these components for the particular case where P lies on the rim of the hemisphere's base, and for this purpose we will take the origin

$\frac{4}{3} \pi \rho (r_1^3 - r_0^3)$

of our system of polar coördinates at P , because by so doing we shall escape having to deal with a quantity which becomes infinite at one of the limits of integration. Denote the coördinates of any point L in the hemisphere by r, θ, ϕ , where (Fig. 9) $XPN = \phi$, $IPL = \theta$, and $PL = r$.

FIG. 9.

If r_1 be the radius of the hemisphere,

$$PT = PN \cos NPT = PX \cos XPN \cdot \cos NPT = 2r_1 \sin \theta \cos \phi.$$

$$\cos XPL = \frac{IK}{PL} = \frac{IK}{r} = \frac{IL \cos \phi}{r} = \sin \theta \cos \phi.$$

$$\cos SPL = \frac{PS}{PL} = \frac{KL}{r} = \frac{IL \sin \phi}{r} = \sin \theta \sin \phi.$$

The mass of a polar element of volume whose corner is at L is approximately $\rho \cdot IL \Delta \phi \cdot PL \Delta \theta \cdot \Delta r$ or $\rho r^2 \sin \theta \Delta r \Delta \theta \Delta \phi$, and this divided by r^2 is the attraction at P in the direction PL of the element, supposed concentrated at L . The components of this attraction in the direction PX and PY are respectively $\rho \sin \theta \Delta r \Delta \theta \Delta \phi \cos XPL$ and $\rho \sin \theta \Delta r \Delta \theta \Delta \phi \cos SPL$.

The component in the direction PY of the attraction at P due to the whole hemisphere is, then,

$$\int_0^{\pi} \frac{\pi}{2} d\phi \int_0^{\pi} d\theta \int_0^{2r_1 \sin \theta \cos \phi} \rho \sin^2 \theta \sin \phi dr = \frac{4}{3} \rho r_1, \quad [27]$$

$$AP = r$$

$$CAQ = \theta$$

$$RAB = \phi$$

c Elementary volume at P

$$= r d\theta \cdot r \sin\theta d\phi \cdot dr = r^2 \sin\theta d\phi d\theta dr$$

Along AB component $= \iiint \rho \frac{r^2 \sin\theta d\phi d\theta dr}{r^2} \sin\theta \cos\phi$

$$= \rho \int_0^{\frac{\pi}{2}} d\phi \int_0^{\pi} d\theta \int_0^{2a} \frac{2a \sin\theta \cos\phi}{\sin^2\theta \cos\phi} dr = \frac{2}{3} \rho a \pi$$

Along AD component is

$$\rho \int_0^{\pi} d\theta \int_0^{\frac{\pi}{2}} d\phi \int_0^{2a} \frac{2a \sin\theta \cos\phi}{\sin^2\theta \cdot \sin\phi} dr = \frac{4}{3} \rho a$$

[Thomson + Tait II, §478 -

and the component in the direction Px is

$$\int_0^{\frac{\pi}{2}} d\phi \int_0^{\pi} d\theta \int_0^{2r_1} \rho \sin^2 \theta \cos \phi dr = \frac{2}{3} \pi \rho r_1. \quad [28]$$

This last expression might have been obtained from [26] by making c equal to r and halving the result.

11. Attraction of a Hemispherical Hill. If at a point on the earth at the southern extremity of a homogeneous hemispherical hill of density ρ and radius r_1 the force of gravity due to the earth, supposed spherical, is g , the attraction due to the earth and the hill will give rise to two components, $g - \frac{4}{3} \rho r_1$ downwards, and $\frac{2}{3} \pi \rho r_1$ northwards. The resultant attraction does not therefore act in the direction of the centre of the earth, but makes with this direction an angle whose tangent is $\frac{\frac{2}{3} \pi \rho r_1}{g - \frac{4}{3} \rho r_1}$.

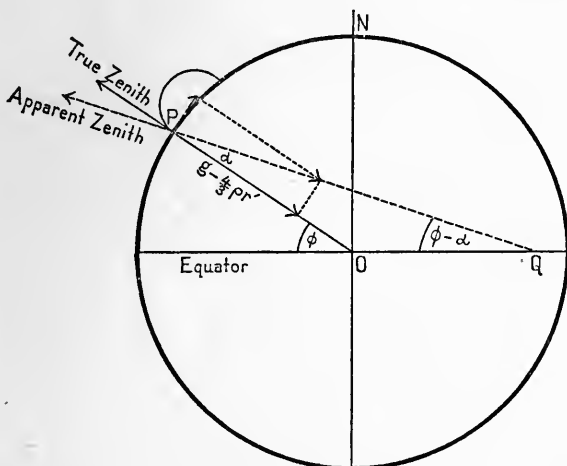

FIG. 10.

Let ϕ (Fig. 10) be the true latitude of the place and $(\phi - \alpha)$ the apparent latitude, as obtained by measuring the angle which the plumb-line at the place makes with the plane of the equator. Let a be the radius of the earth and σ its average density. Then

$$\tan \alpha = \frac{\frac{2}{3} \pi \rho r_1}{g - \frac{4}{3} \rho r_1} = \frac{\pi \rho r_1}{2(\pi a \sigma - \rho r_1)}. \quad [29]$$

$$g = \frac{\frac{4}{3} \pi \sigma a^3}{a^2} = \frac{4}{3} \pi \sigma a$$

The radius of the earth is very large compared with the radius of the hill, and α is a small angle, so that approximately $\alpha = \frac{\rho r_1}{2 a \sigma}$, and the apparent latitude of the place is $\phi - \frac{\rho r_1}{2 a \sigma}$.

If ϕ_1 is the true latitude of a place just north of the same hill, its apparent latitude will be $\phi_1 + \frac{\rho r_1}{2 a \sigma}$, and the apparent difference of latitude between the two places, one just north of the hill and the other just south of it, will be the true difference plus $\frac{\rho r_1}{a \sigma}$. If there were a hemispherical cavity between the two places instead of a hemispherical hill, the apparent difference of latitude would be less than the true difference.

12. Ellipsoidal Homœoids. A shell, thick or thin, bounded by two ellipsoidal surfaces, concentric, similar, and similarly placed, shall be called an *ellipsoidal homœoid*.

FIG. 11.

It is a property of every such shell that if any straight line cut its outer surface at the points S, S' (Fig. 11) and its inner surface at Q, Q' , so that these four points lie in the order $SQQ'S'$, the length SQ will be equal to the length $Q'S'$.

We will prove that the attraction of a homogeneous closed

ellipsoidal homœoid, at any point P in the cavity which it shuts in, is zero.

Make P the vertex of a slender conical surface of two nappes, A and B , and suppose the plane of the paper to be so chosen that PQ is the shortest and PM the longest length cut from any element of the nappe A by the inner surface of the homœoid. Draw about P spherical surfaces of radii PQ , PM , PS , and PO , and imagine the space between the innermost and outermost of these surfaces filled with matter of the same density as the homœoid. The nappe A cuts out a portion from this spherical shell whose trace on the plane of the paper is $QLOT$. Let us call this, for short, "the element $QLOT$." The attraction at P , due to the element $QMOS$ which A cuts out of the homœoid, is less than the attraction at the same point due to the element $QLOT$, and greater than that due to the element whose trace is $KMNS$. But the attraction at P , due to the first of these elements of spherical shells, is to the attraction due to the other as the thickness of the first shell is to that of the other, or as QT is to KS . (See Section 8.) The limit of the ratio of QT to KS , as the solid angle of the cone is made smaller and smaller, is unity; therefore the limit of the ratio of the attraction at P due to the element $QMOS$, to the attraction due to the element of spherical shell whose trace is $QLNS$, is unity. By a similar construction it is easy to show that the limit of the ratio of the attraction at P , due to the element which B cuts out of the homœoid, to the attraction due to the portion of spherical shell whose trace is $Q'L'N'S'$, is unity.

But the attractions at P , due to the elements $Q'L'N'S'$ and $QLNS$, are equal in amount (since their thicknesses are the same) and opposite in direction, so that if for the elements of the homœoid these elements were substituted, there would be no resultant attraction at P . In order to get the attraction at P in any direction due to the whole homœoid we may cut up the inner surface of the homœoid into elements, use the perimeter of each one of these elements as the directrix of a conical sur-

face having its vertex at P , and find the limit of the sum of the attractions due to the elements which these conical surfaces cut from the homœoid. Wherever we have to find the finite limit of the sum of a series of infinitesimal quantities, we may without error substitute for any one of these another infinitesimal, the limit of whose ratio to the first is unity. For the attractions at P due to the elements of the homœoid we may, therefore, substitute attractions due to elements of spherical shells, which, as we have seen, destroy each other in pairs. Hence our proposition.

A shell bounded by two concentric spherical surfaces gives a special case under this theorem.

13. Sphere of Variable Density. The density of a homogeneous body is the amount of matter contained in the unit volume of the material of which the body is composed, and this may be obtained by dividing the mass of the body by its volume.

If the amount of matter contained in a given volume is not the same throughout a body, the body is called heterogeneous, and its density is said to be variable.

The average density of a heterogeneous body is the ratio of the mass of the body to its volume. The actual density ρ at any point Q inside the body is defined to be the limit of the ratio of the mass of a small portion of the body taken about Q to the volume of this portion as the latter is made smaller and smaller.

The attraction, at any point P , due to a spherical shell whose density is the same at all points equidistant from the common centre of the spherical surfaces which bound the shell but different at different distances from this centre, may be obtained with the help of some of the equations in Article 9.

Since ρ is independent of θ and ϕ , it may be taken out from under the signs of integration with regard to these variables, although it must be left under the sign of integration with regard to r .

Equations 19 to 24 inclusive hold for the case that we are now considering as well as for the case when ρ is constant,

so that the attraction at all points within the cavity enclosed by a spherical shell whose density varies with the distance from the centre is zero.

If P is without the shell, the attraction is

$$\int_{r_0}^{r_1} \frac{4\pi\rho r^2 dr}{c^2},$$

or, if $\rho = f(r)$,

$$\frac{4\pi}{c^2} \int_{r_0}^{r_1} f(r) \cdot r^2 dr. \tag{30}$$

The mass of the shell is evidently

$$\lim_{\Delta r \rightarrow 0} \sum_{r_0}^{r_1} 4\pi r^2 \cdot f(r) dr = 4\pi \int_{r_0}^{r_1} f(r) \cdot r^2 dr, \tag{31}$$

and [30] declares that a spherical shell whose density is a function of the distance from its centre attracts at all outside points as if the whole mass of the shell were concentrated at the centre.

If $r_0 = 0$, we have the case of a solid sphere.

14. Attraction due to any Mass. In order to find the attraction at a point P (Fig. 12), due to any attracting masses M' , we may choose a system of rectangular coördinate axes and divide

FIG. 12.

M' up into volume elements. If ρ is the average density of one of these elements ($\Delta v'$), the mass of the element will be $\rho\Delta v'$. Let Q , whose coördinates are x', y', z' , be a point of the ele-

ment, and let the coördinates of P be x, y, z . The attraction at P in the direction PQ due to this element is approximately $\frac{\rho \Delta v'}{PQ^2}$, and the components of this in the direction of the coördinate axes are

$$\frac{\rho \Delta v'}{PQ^2} \cos \alpha', \quad \frac{\rho \Delta v'}{PQ^2} \cos \beta', \quad \text{and} \quad \frac{\rho \Delta v'}{PQ^2} \cos \gamma', \quad [32]$$

where α', β', γ' are the angles which PQ makes with the positive directions of the axes.

It is easy to see that

$$\cos \alpha' = \frac{PL}{PQ} = \frac{x' - x}{PQ},$$

and, similarly, that

$$\cos \beta' = \frac{y' - y}{PQ}, \quad \text{and} \quad \cos \gamma' = \frac{z' - z}{PQ}.$$

Moreover,

$$\overline{PQ^2} = \overline{PL^2} + \overline{LS^2} + \overline{SQ^2} = (x' - x)^2 + (y' - y)^2 + (z' - z)^2,$$

and this we will call r^2 .

The true values of the components in the direction of the coördinate axes of the attraction at P , due to all the elements which go to make up M' , are, then,

$$\begin{aligned} X &= \lim_{\Delta v' \doteq 0} \sum \frac{\rho \Delta v' (x' - x)}{r^3} \quad \left\{ \frac{dm}{r^2} \cdot \frac{z' - z}{r} \right. \\ &= \iiint \frac{\rho (x' - x) dx' dy' dz'}{[(x' - x)^2 + (y' - y)^2 + (z' - z)^2]^{\frac{3}{2}}}; \quad [33_A] \end{aligned}$$

$$\begin{aligned} Y &= \lim_{\Delta v' \doteq 0} \sum \frac{\rho \Delta v' (y' - y)}{r^3} \\ &= \iiint \frac{\rho (y' - y) dx' dy' dz'}{[(x' - x)^2 + (y' - y)^2 + (z' - z)^2]^{\frac{3}{2}}}, \quad [33_B] \end{aligned}$$

$$\begin{aligned} Z &= \lim_{\Delta v' \doteq 0} \sum \frac{\rho \Delta v' (z' - z)}{r^3} \\ &= \iiint \frac{\rho (z' - z) dx' dy' dz'}{[(x' - x)^2 + (y' - y)^2 + (z' - z)^2]^{\frac{3}{2}}}; \quad [33_C] \end{aligned}$$

where ρ is the density at the point (x', y', z') , and where the integrations with regard to x' , y' , and z' are to include the whole of M' .

The resultant attraction at P , due to M' , is

$$R = \sqrt{X^2 + Y^2 + Z^2}; \quad [34]$$

and its line of action makes with the coördinate axes angles whose cosines are

$$\lambda = \frac{X}{R}, \quad \mu = \frac{Y}{R}, \quad \text{and} \quad \nu = \frac{Z}{R}. \quad [35]$$

The component of the attraction at the point (x, y, z) in a direction making an angle ϵ with the line of action of R is $R \cos \epsilon$. If the direction cosines of this direction are λ' , μ' , ν' , we have

$$\cos \epsilon = \lambda\lambda' + \mu\mu' + \nu\nu'.$$

15. The quantities X , Y , Z , and R , which occur in the last section, are in general functions of the coördinates x , y , and z of the point P . Let us consider X , whose value is given in [33_A]. If P lies without the attracting mass M' , the quantity $\frac{x' - x}{r^3}$ is finite for all the elements into which M' is divided. Let L be the largest value which it can have for any one of these elements, then X is less than $L \iiint \rho dx' dy' dz'$, or $L \cdot M'$, and this is finite. If P is a point within the space which the attracting mass occupies, it is easy to show that, whatever physical meaning we may attach to X , it has a finite value. To prove this, make P the origin of a system of polar coördinates, and divide M' up into elements like those used in Section 10. It will then be clear that

$$X = \iiint \rho \sin^2 \theta \cos \phi dr d\theta d\phi, \quad [36]$$

where the limits are to be chosen so as to include all the attracting mass. Since $\sin^2 \theta \cos \phi$ can never be greater than

what if $\theta = 90$, $\phi = 1$?

unity, X is less than $\iiint \rho dr d\theta d\phi$, which is evidently finite when ρ is finite, as it always is in fact.

The corresponding expressions,

$$Y = \iiint \rho \sin^2 \theta \sin \phi dr d\theta d\phi, \quad [37]$$

and
$$Z = \iiint \rho \sin \theta \cos \theta dr d\theta d\phi, \quad [38]$$

can be proved finite in a similar manner; and it follows that X , Y , Z , and consequently R , are finite for all values of x , y , and z .

As a special case, the attraction at a point P within the mass of a homogeneous spherical shell, of radii r_0 and r_1 , and of density ρ , is

$$\frac{4}{3} \pi \rho \left(\frac{r^3 - r_0^3}{r^2} \right), \quad [39]$$

where r is the distance of P from the centre of the shell.

16. Attraction between Two Straight Wires. Let AK and BK' (Fig. 13) be two straight wires of lengths l and l' and of line-densities μ and μ' ; and let $KB = c$. Divide AK into

FIG. 13.

elements of length Δx , and consider one of these MM' , such that $AM = x$. The attraction of BK' on a unit mass concentrated at M would be (Sections 2 and 5), $\mu' \left[\frac{1}{MB} - \frac{1}{MK'} \right]$. If, therefore, the whole element MM' whose mass is $\mu \Delta x$ were concentrated at M , the attraction on it, due to BK' , would be

$$\mu \mu' \Delta x \left[\frac{1}{MB} - \frac{1}{MK'} \right] = \mu \mu' \Delta x \left[\frac{1}{l + c - x} - \frac{1}{l + l' + c - x} \right]. \quad [40]$$

The actual force, due to the attraction of BK' , with which the whole wire AK is urged toward the right, is

$$\begin{aligned} & \lim_{\Delta x \rightarrow 0} \sum_0^l \mu \mu' \Delta x \left[\frac{1}{l+c-x} - \frac{1}{l+l'+c-x} \right] \\ &= \mu \mu' \int_0^l \left(\frac{1}{x-(l+l'+c)} - \frac{1}{x-(l+c)} \right) dx \\ &= \mu \mu' \left[\log \frac{x-l-l'-c}{x-l-c} \right]_0^l = \mu \mu' \log \frac{(l+c)(l'+c)}{c(l+l'+c)}. \quad [41] \end{aligned}$$

17. Attraction between Two Spheres. Consider two homogeneous spheres of masses M and M' (Fig. 14), whose centres C and C' are at a distance c from each other. Divide the sphere M' into elements in the manner described in Section 9. The attraction due to M at any point P' outside of this sphere is, as we have seen, $\frac{M}{CP'^2}$, and its line of action is in the direction $P'C$.

FIG. 14.

Let $P' = (r, \theta, \phi)$ be any point in the sphere M' , and let $CP' = y$. The attraction of M in the direction $P'C$ on an element of mass $\rho r^2 \sin \theta \Delta r \Delta \theta \Delta \phi$ supposed concentrated at P' is $\frac{M \rho r^2 \sin \theta \Delta r \Delta \theta \Delta \phi}{y^2}$, and the component of this parallel to the line $C'C$ is $\frac{M \rho r^2 \sin \theta (c - r \cos \theta) \Delta r \Delta \theta \Delta \phi}{y^3}$. The force with

which the whole sphere M' is urged toward the right by the attraction of M is, then,

$$M \iiint \frac{\rho r^2 \sin \theta dr d\theta d\phi (c - r \cos \theta)}{y^3}, \quad [42]$$

where the integration is to be extended to all the elements which go to make up M' . It is proved in Section 9 that the value of this triple integral is $\frac{M'}{c^2}$, so that the force of attraction between the two spheres is $\frac{MM'}{c^2}$.

18. Attraction between any Two Rigid Bodies. In order to find the force with which a rigid body M is pulled in any direction (as for instance in that of the axis of x) by the attraction of another body M' , we must in general find the value of a sextuple integral.

Let M be divided up into small portions, and let Δm be the mass of one of these elements which contains the point (x, y, z) .

The component in the direction of the axis of x of the attraction at (x, y, z) due to M' is

$$\iiint \frac{\rho (x' - x) dx' dy' dz'}{[(x' - x)^2 + (y' - y)^2 + (z' - z)^2]^{\frac{3}{2}}},$$

and this would be the actual attraction in this direction on a unit mass supposed concentrated at (x, y, z) . If the mass Δm were concentrated at this point, the attraction on it in the direction of the axis of x would be

$$\Delta m \iiint \frac{\rho (x' - x) dx' dy' dz'}{[(x' - x)^2 + (y' - y)^2 + (z' - z)^2]^{\frac{3}{2}}}. \quad [43]$$

The actual attraction in the direction of the axis of x of M' upon the whole of M is, then,

$$\lim_{\Delta m \doteq 0} \sum \Delta m \cdot \iiint \frac{\rho (x' - x) dx' dy' dz'}{[(x' - x)^2 + (y' - y)^2 + (z' - z)^2]^{\frac{3}{2}}}. \quad [44]$$

[The page contains extremely faint, illegible handwritten text, likely bleed-through from the reverse side of the paper. The text is too light to transcribe accurately.]

Examples-

$$\text{Att}^n = \frac{2\mu}{c} \cos \frac{1}{2}(\delta + \delta') = \text{const} =$$

$$\text{+ here } c = y$$

$$\therefore \cos \frac{1}{2}(\delta + \delta') = \frac{k}{2\mu} y = c' y$$

$$\therefore \cos(\delta + \delta') = 2c'^2 y^2 - 1$$

$$\text{or } \cos \delta \cos \delta' - \sin \delta \sin \delta' = 2c'^2 y^2 - 1$$

$$\text{or } \frac{l+x}{\sqrt{y^2+(l+x)^2}} \cdot \frac{l-x}{\sqrt{y^2+(l-x)^2}} - \frac{y}{\sqrt{y^2+(l+x)^2}} \cdot \frac{y}{\sqrt{y^2+(l-x)^2}} = 2c'^2 y^2$$

$$\text{or } \frac{l^2 - x^2 - y^2}{\{y^2+(l+x)^2\}^{\frac{1}{2}} \{y^2+(l-x)^2\}^{\frac{1}{2}}} = 2c'^2 y^2 - 1$$

4.

Consider a slender cone, vertex P
let dS , dS' be traces on AB, CD.

Attⁿ of dS on particle at P

$$= \frac{\rho \tau dS}{r^2};$$

$$\text{that of } dS' = \frac{\rho \tau dS'}{r'^2}$$

$$\text{But } dS/dS' = r^2 : r'^2$$

\therefore these attractions are equal.

\therefore attⁿ of plates of equal thickness are equal.

$$\text{or: Element of att}^n = \frac{\rho \tau^2 \sin \theta \cdot dr d\theta d\phi}{r^2}$$

$$= \rho \sin \theta \cdot dr \cdot d\theta d\phi$$

wh. depends only on dr , not on r , so

long as θ & ϕ are const. (See Munching p. 2)

If ρ' is the density at the point (x', y', z') , and if the elements into which M is divided are rectangular parallelepipeds of dimensions Δx , Δy , and Δz , the expression just given may be written

$$\iiint \iiint \frac{\rho' \rho (x' - x) dx' dy' dz'}{[(x' - x)^2 + (y' - y)^2 + (z' - z)^2]^{\frac{3}{2}}}, \quad [45]$$

where the integrations are first to be extended over M' and then over M .

$$x = \frac{12}{25} \cdot \frac{3}{5} - \frac{16}{169} \cdot \frac{5}{13} + \frac{20}{100} \cdot \frac{8}{10} = \frac{113,032}{274,625}$$

EXAMPLES.
$$Y = \frac{12}{25} \cdot \frac{4}{5} + \frac{16}{169} \cdot \frac{12}{13} - \frac{20}{100} \cdot \frac{6}{10} =$$

✓ 1. Find the resultant attraction, at the origin of a system of rectangular coördinates, due to masses of 12, 16, and 20 units respectively, concentrated at the points (3, 4), (-5, 12), and (8, -6). What is its line of action?

$\tan \theta = \frac{Y}{X}$
 $R = \sqrt{X^2 + Y^2}$

✓ 2. Find the value, at the origin of a system of rectangular coördinates, of the attraction due to three equal spheres, each of mass m , whose centres are at the points $(a, 0, 0)$, $(0, b, 0)$, $(0, 0, c)$. Find also the direction-cosines of the line of action of this resultant attraction.

$x = \frac{m}{a^2}$
 $Y = \frac{m}{b^2}$
 $Z = \frac{m}{c^2}$
 $R = \sqrt{x^2 + Y^2 + Z^2}$
 $\cos \alpha = \frac{x}{R}$; $\cos \beta = \frac{Y}{R}$

✓ 3. Show that the attraction, due to a uniform wire bent into the form of the arc of a circumference, is the same at the centre of the circumference as the attraction due to any uniform straight wire of the same density which is tangent to the given wire, and is terminated by the bounding radii (when produced) of the given wire.

$At = \int \frac{\mu \cdot ds}{a^2} \cos \theta$
 $= \int \frac{\mu \cdot a \cdot d\theta \cdot \cos \theta}{a^2}$
 $= \frac{2\mu a}{a^2} \sin \theta$
 $= \frac{2\mu \sin \theta}{a}$

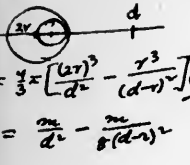

✓ 4. Show that in the case of an oblique cone whose base is any plane figure the attraction at the vertex of the cone due to any frustum varies, other things being equal, as the thickness of the frustum.

✓ 5. Find the equation of a family of surfaces over each one of which the resultant force of attraction due to a uniform straight wire is constant.

✓ 6. Using the foot-pound-second system of fundamental units, and assuming that the average density of the earth is 5.6, compare with the poundal the unit of force used in this chapter.

$32.2 \text{ pdls} = \frac{4}{3} \cdot \pi \cdot 3960 \times 5280 \times 5.6 \times 62.5 \text{ grav. units.}$
 $\therefore 1 \text{ pdl} = 952,000,000 \text{ attrac}^n \text{ units. (ft. lb.)}$
 $= 951,980,000$

7. If in Fig. 2 we suppose P moved up to A , the attraction at P becomes infinite according to [7], and yet Section 15 asserts that the value, at any point inside a given mass, of the attraction due to this mass is always finite. Explain this.

8. A spherical cavity whose radius is r is made in a uniform sphere of radius $2r$ and mass m in such a way that the centre of the sphere lies on the wall of the cavity. Find the attraction due to the resulting solid at different points on the line joining the centre of the sphere with the centre of the cavity.

9. A uniform sphere of mass m is divided into halves by the plane AB passed through its centre C . Find the value of the attraction due to each of these hemispheres at P , a point on the perpendicular erected to AB at C , if $CP = a$.

$$t \propto \frac{1}{2}$$

$$g_1 = \frac{4\pi}{n+3} a_1^{n+1}$$

$$g_2 = \frac{4\pi}{n+3} a_2^{n+1}$$

$$\therefore a_1^{n+1} = a_2^{n+1}$$

$$\therefore n+1 = 0$$

10. Considering the earth a sphere whose density varies only with the distance from the centre, what may we infer about the law of change of this density if a pendulum swing with the same period on the surface of the earth and at the bottom of a deep mine? What if the force of attraction increases with the depth at the rate of $\frac{1}{n}$ th of a dyne per centimetre of descent?

11. The attraction due to a cylindrical tube of length h and of radii R_0 and R_1 , at a point in the axis, at a distance c_0 from the plane of the nearer end, is

$$2\pi\rho[\sqrt{c_0^2 + R_1^2} - \sqrt{c_0^2 + R_0^2} + \sqrt{(c_0+h)^2 + R_0^2} - \sqrt{(c_0+h)^2 + R_1^2}].$$

[Stone.]

12. A spherical cavity of radius b is hollowed out in a sphere of radius a and density ρ , and then completely filled with matter, of density ρ_0 . If c is the distance between the centre of the cavity and the centre of the sphere, the attraction due to the composite solid at a point in the line joining these two centres, at a distance d from the centre of the sphere, is

$$\frac{4}{3}\pi\left[\frac{\rho a^3}{d^2} + \frac{b^3(\rho_0 - \rho)}{(d \pm c)^2}\right].$$

[Stone.]

13. The centre of a sphere of aluminum of radius 10 and of density 2.5, is at the distance 100 from a sphere of the same

$$\frac{2.15}{x^2} = \frac{19}{(100-x)^2}$$

$$\therefore x = 76.6$$

size made of gold, of density 19. Show that the attraction due to these spheres is nothing at a point between them, at a distance of about 26.6 from the centre of the aluminum sphere.

[Stone.]

14. Show that the attraction at the centre of a sphere of radius r , from which a piece has been cut by a cone of revolution whose vertex is at the centre, is $\pi\rho r^3 \sin^2\alpha$, where α is the half angle of the cone.

[Stone.]

15. An iron sphere of radius 10 and density 7 has an eccentric spherical cavity of radius 6, whose centre is at a distance 3 from the centre of the sphere. Find the attraction due to this solid at a point 25 units from the centre of the sphere, and so situated that the line joining it with this centre makes an angle of 45° with the line joining the centre of the sphere and the centre of the cavity.

[Stone.]

16. If the piece of a spherical shell of radii r_0 and r_1 , intercepted by a cone of revolution whose solid angle is ω and whose vertex is the centre of the shell, be cut out and removed, find the attraction of the remainder of the shell at a point P situated in the axis of the cone at a given distance from the centre of the sphere. If in the vertical shaft of a mine a pendulum be swung, is there any appreciable error in assuming that the only matter whose attraction influences the pendulum lies nearer the centre of the earth, supposed spherical, than the pendulum does?

17. Show that the attraction of a spherical segment is, at its vertex,

$$2\pi k\rho \left\{ 1 - \frac{1}{3} \sqrt{\frac{2h}{a}} \right\},$$

where a is the radius of the sphere and h the height of the segment.

18. Show that the resultant attraction of a spherical segment on a particle at the centre of its base is

$$\frac{2\pi h\rho}{3(a-h)^2} [3a^2 - 3ah + h^2 - (2a-h)^{\frac{3}{2}}h^{\frac{1}{2}}].$$

√ 19. Show that the attraction at the focus of a segment of a paraboloid of revolution bounded by a plane perpendicular to the axis at a distance b from the vertex is of the form

$$4\pi\rho a \log \frac{a+b}{a}.$$

20. Show that the attraction of the oblate spheroid formed by the revolution of the ellipse of semiaxes a , b , and eccentricity e , is, at the pole of the spheroid,

$$\frac{4\pi\rho b}{e^2} \left\{ 1 - \frac{(1-e^2)^{\frac{1}{2}}}{e} \sin^{-1} e \right\},$$

and that the attraction due to the corresponding prolate spheroid is, at its pole,

$$\frac{4\pi\rho a(1-e^2)}{e^2} \left\{ \frac{1}{2e} \log \frac{1+e}{1-e} - 1 \right\}.$$

21. Show that the attraction at the point $(c, 0, 0)$, due to the homogeneous solid bounded by the planes $x = a$, $x = b$, and by the surface generated by the revolution about the axis of x of the curve $y = f(x)$, is

$$2\pi\rho \int_a^b \left\{ 1 + \frac{c-x}{[(c-x)^2 + (fx)^2]^{\frac{1}{2}}} \right\} dx.$$

22. Prove that the attraction of a uniform lamina in the form of a rectangle, at a point P in the straight line drawn through the centre of the lamina at right angles to its plane, is

$$4\mu \sin^{-1} \frac{ab}{\sqrt{a^2 + c^2} \sqrt{b^2 + c^2}},$$

where $2a$ and $2b$ are the dimensions of the lamina and c the distance of P from its plane. [See Todhunter's *Analytical Statics*.]

CHAPTER II.

THE NEWTONIAN POTENTIAL FUNCTION IN THE CASE OF GRAVITATION.

19. Definition. If we imagine an attracting body M to be cut up into small elements, and add together all the fractions formed by dividing the mass of each element by the distance of one of its points from a given point P in space, the limit of this sum, as the elements are made smaller and smaller, is called the value at P of "the potential function due to M ."

If we call this quantity V , we have

$$V = \lim_{\Delta m \rightarrow 0} \sum \frac{\Delta m}{r}, \quad [46]$$

where Δm is the mass of one of the elements and r its distance from P , and where the summation is to include all the elements which go to make up M .

If we denote by $\bar{\rho}$ the average density of the element whose mass is Δm , and call the coördinates of the corner of this element nearest the origin x', y', z' , and those of P , x, y, z , we may write

$$\Delta m = \bar{\rho} \Delta x' \Delta y' \Delta z',$$

and

$$V = \iiint \frac{\rho dx' dy' dz'}{[(x' - x)^2 + (y' - y)^2 + (z' - z)^2]^{\frac{3}{2}}}, \quad [47]$$

where ρ is the density at the point (x', y', z') , and where the triple integration is to include the whole of the attracting mass M .

As the position of the point P changes, the value of the quantity under the integral signs in [47] changes, and in general V is a function of the three space coördinates, *i.e.*, $V = f(x, y, z)$.

To avoid circumlocution, a point at which the value of the

potential function is V_0 is sometimes said to be "at potential V_0 ." From the definition of V it is evident that if the value at a point P of the potential function due to a system of masses M_1 existing alone is V_1 , and if the value at the same point of the potential function due to another system of masses M_2 existing alone is V_2 , the value at P of the potential function due to M_1 and M_2 existing together is $V = V_1 + V_2$.

20. The Derivatives of the Potential Function. If P is a point outside the attracting mass, the quantity

$$\sqrt{(x' - x)^2 + (y' - y)^2 + (z' - z)^2}, \quad \text{r. e. } r$$

which enters into the expression for V in [47], can never be zero, and the quantity under the integral signs is finite everywhere within the limits of integration; now, since these limits depend only upon the shape and position of the attracting mass and have nothing to do with the coördinates of P , we may differentiate V with respect to either x , y , or z by differentiating under the integral signs. Thus:

$$\begin{aligned} D_x V &= \iiint D_x \left[\frac{\rho dx' dy' dz'}{r} \right] \\ &= \iiint \frac{\rho (x' - x) dx' dy' dz'}{[(x' - x)^2 + (y' - y)^2 + (z' - z)^2]^{\frac{3}{2}}}, \end{aligned} \quad [48]$$

where the limits of integration are unchanged by the differentiation. The dexter integral in this equation is (Section 14) the value of the component parallel to the axis of x of the attraction at P due to the given masses, so that we may write, using our old notation,

$$D_x V = X, \quad [49]$$

and, similarly, $D_y V = Y, \quad [50]$

$$D_z V = Z. \quad [51]$$

The resultant attraction at P is

$$R = \sqrt{X^2 + Y^2 + Z^2} = \sqrt{(D_x V)^2 + (D_y V)^2 + (D_z V)^2}, \quad [52]$$

and the direction-cosines of its line of action are :

$$\cos \alpha = \frac{D_x V}{R}, \quad \cos \beta = \frac{D_y V}{R}, \quad \text{and} \quad \cos \gamma = \frac{D_z V}{R}. \quad [53]$$

It is evident from the definition of the potential function that the value of the latter at any point is independent of the particular system of rectangular axes chosen. If, then, we wish to find the component, in the direction of any line, of the attraction at any point P , we may choose one of our coördinate axes parallel to this line, and, after computing the general value of V , we may differentiate the latter partially with respect to the coördinate measured on the axis in question, and substitute in the result the coördinates of P .

21. Theorem. The results of the last section may be summed up in the words of the following

THEOREM.

To find the component at a point P , in any direction PK , of the attraction due to any attracting mass M , we may divide the difference between the values of the potential function due to M at P' (a point between P and K on the straight line PK) and at P by the distance PP' . The limit approached by this fraction as P' approaches P is the component required.

We might have arrived at this theorem in the following way :

If X, Y, Z are the components parallel to the coördinate axes of the attraction at any point P , the component in any direction PK whose direction-cosines are $\lambda, \mu,$ and $\nu,$ is

$$R \cos \epsilon = \lambda X + \mu Y + \nu Z = \lambda D_x V + \mu D_y V + \nu D_z V. \quad [54]$$

Let x, y, z be the coördinates of P , and $x + \Delta x, y + \Delta y, z + \Delta z$ those of P' , a neighboring point on the line PK .

If V and V' are the values of the potential function at P and P' respectively, we have, by Taylor's Theorem,

$$V' = V + \Delta x \cdot D_x V + \Delta y \cdot D_y V + \Delta z \cdot D_z V + \epsilon,$$

where ϵ is an infinitesimal of an order higher than the first.

$$\frac{V' - V}{PP'} = \frac{\Delta x}{PP'} \cdot D_x V + \frac{\Delta y}{PP'} \cdot D_y V + \frac{\Delta z}{PP'} \cdot D_z V + \frac{\epsilon}{PP'}; \quad [55]$$

but $\Delta x = \lambda \cdot PP'$, $\Delta y = \mu \cdot PP'$, $\Delta z = \nu \cdot PP'$,

$$\text{therefore, } \lim_{PP' \rightarrow 0} \left(\frac{V' - V}{PP'} \right) = \lambda D_x V + \mu D_y V + \nu D_z V, \quad [56]$$

and this (see [54]) is the component in the direction PK of the attraction at P : which was to be proved.

22. The Potential Function everywhere Finite. If P is a point within the attracting mass, the sum whose limit expresses the value of the potential function at P contains one apparently infinite term. That V is not infinite in this case is easily proved by making P the origin of a system of polar coördinates as in Section 15, when it will appear that the value of the potential function at P can be expressed in the form

$$V_P = \iiint \rho r \sin \theta \, dr \, d\theta \, d\phi; \quad [57]$$

and this is evidently finite.

$$= \sum \frac{r \sin \theta \, d\phi \cdot r \, d\theta \cdot dr}{r}$$

Although V_P is everywhere finite, yet when we express its value by means of the equation [47], the quantity under the integral signs becomes infinite within the limits of integration,

FIG. 15.

when P is a point inside the attracting mass. Under these circumstances we cannot assume without further proof that the result obtained by differentiating with respect to x under the integral signs is really $D_x V$. It is therefore desirable to com-

pute the limit of the ratio of the difference ($\Delta_x V$) between the values of V at the points $P' = (x + \Delta x, y, z)$ and $P = (x, y, z)$, both within the attracting mass, to the distance (Δx) between these points. For convenience, draw through P (Fig. 15) three lines parallel to the coördinate axes, and let $Q = (x', y', z')$.

Let $PQ = r$, $P'Q = r'$, and $\angle P'PQ = \psi$.

Then

$$r'^2 = r^2 + (\Delta x)^2 - 2r \cdot \Delta x \cdot \cos \psi,$$

where $\cos \psi = \frac{x' - x}{r},$

and
$$\begin{aligned} \frac{\Delta_x V}{\Delta x} &= \iiint \left(\frac{1}{r'} - \frac{1}{r} \right) \frac{\rho dx' dy' dz'}{\Delta x} \\ &= \iiint \left(\frac{r^2 - r'^2}{r' r^2 + r r'^2} \right) \frac{\rho dx' dy' dz'}{\Delta x} \\ &= \iiint \left(\frac{2r \Delta x \cos \psi - (\Delta x)^2}{r' r^2 + r r'^2} \right) \frac{\rho dx' dy' dz'}{\Delta x}. \end{aligned}$$

Therefore

$$\begin{aligned} D_x V &= \lim_{\Delta x \rightarrow 0} \left(\frac{\Delta_x V}{\Delta x} \right) \\ &= \iiint \frac{2r \cos \psi}{r^3} \cdot \rho dx' dy' dz' \\ &= \iiint \frac{\rho dx' dy' dz' \cos \psi}{r^2}. \end{aligned} \tag{58}$$

This last integral is evidently the component parallel to the axis of x of the attraction at P , so that the theorem of Article 21 may be extended to points within the attracting mass.

It is to be noticed that ρ is a function of $x', y',$ and $z',$ but not a function of $x, y,$ and $z,$ and that we have really proved that the derivatives with regard to $x, y,$ and z of

$$\iiint \frac{F(x', y', z')}{r} dx' dy' dz',$$

where F is any finite, continuous, and single-valued function of x' , y' , and z' , can always be found by differentiating under the integral signs, whether (x, y, z) is contained within the limits of integration or not.

23. The Potential Function due to a Straight Wire. Let μ be the mass of the unit length of a uniform straight wire AB (Fig. 16) of length $2l$. Take the middle point of the wire for the origin of coördinates, and a line drawn perpendicular to the wire at this point for the axis of x .

FIG. 16.

The value of the potential function at any point $P(x, y)$ in the coördinate plane is, then, according to [47],

$$\begin{aligned} V_P &= \int_{-l}^{+l} \frac{\mu dy'}{[x^2 + (y' - y)^2]^{\frac{3}{2}}} = \mu \left[\log \{ \sqrt{x^2 + (y' - y)^2} + y' - y \} \right]_{-l}^{+l} \\ &= \mu \log \left\{ \frac{l - y + \sqrt{x^2 + (l - y)^2}}{\sqrt{x^2 + (l + y)^2} - l - y} \right\}. \quad [59] \end{aligned}$$

If $r = AP = \sqrt{x^2 + (l - y)^2}$, and $r' = BP = \sqrt{x^2 + (l + y)^2}$, whence $y = \frac{r'^2 - r^2}{4l}$, we may eliminate x and y from [59] and express V_P in terms of r and r' .

Thus:

$$V_P = \mu \log \frac{(r + 2l)^2 - r'^2}{r^2 - (r' - 2l)^2} = \mu \log \frac{r + r' + 2l}{r + r' - 2l}. \quad [60]$$

It is evident from [60] that if P move so as to keep the sum of its distances from the ends of the wire constant, V_P will

remain constant. P 's locus in this case is an ellipse whose foci are at A and B .

From [59] we get

$$\begin{aligned} D_x V_P &= \frac{\mu}{x} \left[\frac{x^2}{r[r+(l-y)]} - \frac{x^2}{r'[r'-(l+y)]} \right] \\ &= \frac{\mu}{x} \left[\frac{r^2 - (l-y)^2}{r[r+(l-y)]} - \frac{r'^2 - (l+y)^2}{r'[r'-(l+y)]} \right] \\ &= \frac{\mu}{x} \left[\frac{r - (l-y)}{r} - \frac{r' + (l+y)}{r'} \right] \\ &= \frac{\mu}{x} [1 - \cos \delta - 1 - \cos \delta'] \\ &= -\frac{\mu}{x} [\cos \delta + \cos \delta'], \end{aligned}$$

and this (Section 6) is the component in the direction of the axis of x of the attraction at P .

24. The Potential Function due to a Spherical Shell. In order to find the value at the point P of the potential function due to a homogeneous spherical shell of density ρ and of radii r_0 and r_1 , we may make use of the notation of Section 9.

$$\begin{aligned} V &= \iiint \frac{\rho r^2 \sin \theta \, dr \, d\theta \, d\phi}{y} = \iiint \frac{\rho r \, dy \, dr \, d\phi}{c} \\ &= \frac{2\pi\rho}{c} \int_{r_0}^{r_1} r \, dr \int_{y_0}^{y_1} dy. \end{aligned} \quad [61]$$

$y^2 = c^2 + r^2 - 2cr \cos \theta$
 $y \, dy = cr \sin \theta \, d\theta$

If P lies within the cavity enclosed by the shell, the limits of y are $(r - c)$ and $(r + c)$, whence

$$V = 2\pi\rho(r_1^2 - r_0^2). \quad [62]$$

If P lies without the shell, the limits of y are $(c - r)$ and $(c + r)$, whence

$$V = \frac{4}{3}\pi\rho \frac{(r_1^3 - r_0^3)}{c}. \quad [63]$$

If P is a point within the mass of the shell itself, at a distance c from the centre, we may divide the shell into two parts

by means of a spherical surface drawn concentric with the given shell so as to pass through P . The value of the potential function at P is the sum of the components due to these portions of the shell; therefore

$$\begin{aligned} V &= 2\pi\rho(r_1^2 - c^2) + \frac{4}{3} \frac{\pi\rho}{c} (c^3 - r_0^3) \\ &= 2\pi\rho \left\{ r_1^2 - \frac{c^2}{3} \right\} - \frac{4\pi\rho}{3c} r_0^3. \end{aligned} \quad [64]$$

If we put these results together; we shall have the following table:—

	<i>Within cavity</i>	<i>In the substance</i>	<i>Beyond shell</i>
	$c < r_0$	$r_0 < c < r_1$	$r_1 < c$
$V =$	$2\pi\rho(r_1^2 - r_0^2)$	$2\pi\rho\left(r_1^2 - \frac{c^2}{3}\right) - \frac{4\pi\rho}{3c}r_0^3$	$\frac{4\pi\rho}{3c}(r_1^3 - r_0^3)$
$D_c V =$	0	$\frac{4\pi\rho}{3}\left(\frac{r_0^3}{c^2} - c\right)$	$-\frac{4\pi\rho}{3c^2}(r_1^3 - r_0^3)$
$D_c^2 V =$	0	$-\frac{4\pi\rho}{3}\left(\frac{2r_0^3}{c^3} + 1\right)$	$\frac{8\pi\rho}{3c^3}(r_1^3 - r_0^3)$

If we make V , $D_c V$, and $D_c^2 V$ the ordinates of curves whose abscissas are c , we get Fig. 17.*

Here $LNQS$ represents V , and it is to be noticed that this curve is everywhere finite, continuous, and continuous in direction. The curve $OABC$ represents $D_c V$. This curve is everywhere finite and continuous, but its direction changes abruptly when the point P enters or leaves the attracting mass. The three disconnected lines OA , DE , and FG represent $D_c^2 V$.

If the density of the shell instead of being uniform were a function of the distance from the centre [$\rho = f(r)$], we should have at the point P , at the distance c from the centre of the sphere,

$$V = \frac{2\pi}{c} \int_{r_0}^{r_1} f(r) \cdot r \cdot dr \int_{y_0}^{y_1} dy. \quad [65]$$

* See Thomson and Tait's *Treatise on Natural Philosophy*.

From this it follows, as the reader can easily prove, that the value of the potential function due to a spherical shell whose density is a function of the distance from the centre only is

FIG. 17.

This is a typical ca

constant throughout the cavity enclosed by the shell, and at all outside points is the same as if the mass of the shell were concentrated at its centre.

25. Equipotential Surfaces. As we have already seen, V is, in general, a function of the three space coördinates [$V=f(x, y, z)$], and in any given case all these points at which the potential function has the particular value c lie on the surface whose equation is

$$V = f(x, y, z) = c.$$

Such a surface is called an "equipotential" or "level" surface. By giving to c in succession different constant values, the equation $V=c$ yields a whole family of surfaces, and it is always possible to draw through any given point in a field of force a surface at all points of which the potential function has the same value. The potential function cannot have two different values at the same point in space, therefore no two different surfaces of the family $V=c$, where V is the potential function due to an actual distribution of matter, can ever intersect.

But a surface can intersect itself see p. 39 fig

THEOREM.

If there be any resultant force at a point in space, due to any attracting masses, this force acts along the normal to that equipotential surface on which the point lies.

For, let $V = f(x, y, z) = c$ be the equation of the equipotential surface drawn through the point in question, and let the coördinates of this point be x_0, y_0, z_0 . The equation of the plane tangent to the surface at the point is

$$(x - x_0)D_{x_0}V + (y - y_0)D_{y_0}V + (z - z_0)D_{z_0}V = 0,$$

and the direction-cosines of any line perpendicular to this plane, and hence of the normal to the given surface at the point (x_0, y_0, z_0) , are

$$\cos \alpha = \frac{D_{x_0}V}{\sqrt{(D_{x_0}V)^2 + (D_{y_0}V)^2 + (D_{z_0}V)^2}}, \quad [66_a]$$

$$\cos \beta = \frac{D_{y_0}V}{\sqrt{(D_{x_0}V)^2 + (D_{y_0}V)^2 + (D_{z_0}V)^2}}, \quad [66_b]$$

and
$$\cos \gamma = \frac{D_{z_0}V}{\sqrt{(D_{x_0}V)^2 + (D_{y_0}V)^2 + (D_{z_0}V)^2}}. \quad [66_c]$$

But if we denote the resultant force of attraction at the point (x_0, y_0, z_0) by R , and its components parallel to the coördinate axes by X , Y , and Z , these cosines are evidently equal to $\frac{X}{R}$, $\frac{Y}{R}$, and $\frac{Z}{R}$ respectively, so that α , β , and γ are the direction-angles not only of the normal to the equipotential surface at the point (x_0, y_0, z_0) , but also [35] of the line of action of the resultant force at the point. Hence our theorem.

Fig. 18 represents a meridian section of four of the system of equipotential surfaces due to two equal spheres whose sections are here shaded. The value of the potential function due to two spheres, each of mass M , at a point distant respectively r_1 and r_2 from the centres of the spheres, is

$$V = M \left(\frac{1}{r_1} + \frac{1}{r_2} \right),$$

and if we give to V in this equation different constant values, we shall have the equations of different members of the system of equipotential surfaces. Any one of these surfaces may be easily plotted from its equation by finding corresponding values

FIG. 18.

of r_1 and r_2 which will satisfy the equation; and then, with the centres of the two spheres as centres and these values as radii, describing two spherical surfaces. The intersection of these surfaces, if they intersect at all, will be a line on the surface required.

If $2a$ is the distance between the centres of the spheres, $V = \frac{2M}{a}$ gives an equipotential surface shaped like an hour-glass. Larger values of V than this give equipotential surfaces, each one of which consists of two separate closed ovals, one surrounding one of the spheres, and the other the other. Values of V less than $\frac{2M}{a}$ give single surfaces which look more and more like ellipsoids the smaller V is.

Several diagrams showing the forms of the equipotential surfaces due to different distributions of matter are given at

*Though $V = \text{const.}$ over an equipot. surface
 $\frac{dV}{dr}$ is not constant -*

the end of the first volume of Maxwell's *Treatise on Electricity and Magnetism*.

26. The Value of V at Infinity. The value, at the point P , of the potential function due to any attracting mass M has been defined to be

$$V = \lim_{\Delta m \rightarrow 0} \sum \frac{\Delta m}{r}.$$

Let r_0 be the distance of the nearest point of the attracting mass from P , then

$$V < \frac{1}{r_0} \sum \Delta m \text{ or } \frac{M}{r_0}. \quad [67]$$

The fraction $\frac{M}{r_0}$ has a constant numerator, and a denominator which grows larger without limit the farther P is removed from the attracting masses; hence, we see that, other things being equal, the value at P of the potential function is smaller the farther P is from the attracting matter; and that if P be moved away indefinitely, the value of the potential function at P approaches zero as a limit. In other words, *the value of the potential function at "infinity" is zero.*

27. The Potential Function as a Measure of Work. The amount of work required to move a unit mass, concentrated at a point, from one position, P_1 , to another, P_2 , by *any* path, in face of the attraction of a system of masses, M , is equal to

FIG. 19.

$V_1 - V_2$, where V_1 and V_2 are the values at P_1 and P_2 of the potential function due to M .

To prove this, let us divide the given path into equal parts of length Δs , and call the average force which *opposes* the

motion of the unit mass on its journey along one of these elements AB (Fig. 19), F . The amount of work required to move the unit mass from A to B is $F\Delta s$, and the whole work done by moving this mass from P_1 to P_2 will be

$$\lim_{\Delta s \rightarrow 0} \sum_{P_1}^{P_2} F \Delta s.$$

As Δs is made smaller and smaller, the average force opposing the motion along AB approaches more and more nearly the actual opposing force at A , which is $-D_s V$: therefore

$$\lim_{\Delta s \rightarrow 0} \sum_{P_1}^{P_2} F \Delta s = - \int_{P_1}^{P_2} D_s V \cdot ds = V_1 - V_2.$$

It is to be carefully noticed that the *decrease* in the potential function in moving from P_1 to P_2 measures the work required to move the unit mass from P_1 to P_2 . If P_2 is removed farther and farther from M , V_2 approaches zero, and $V_1 - V_2$ approaches V_1 as its limit, so that the value at any point P_1 , of the potential function due to any system of attracting masses, is equal to the work which would be required to move a unit mass, supposed concentrated at P_1 , from P_1 to "infinity" by any path.

The work (W) that must be done in order to move an attracting mass M' against the attraction of any other mass M , from a given position by any path to "infinity," is the sum of the quantities of work required to move the several elements ($\Delta m'$) into which we may divide M' , and this may be written in the form

$$\begin{aligned} W &= \lim_{\Delta m' \rightarrow 0} \sum \Delta m' \iiint \frac{\rho \, dx \, dy \, dz}{[(x' - x)^2 + (y' - y)^2 + (z' - z)^2]^{\frac{3}{2}}} \\ &= \iiint \iiint \iiint \frac{\rho \rho' \, dx \, dy \, dz \, dx' \, dy' \, dz'}{[(x' - x)^2 + (y' - y)^2 + (z' - z)^2]^{\frac{3}{2}}}. \end{aligned} \quad [68]$$

W is called by some writers "the potential of the mass M' with reference to the mass M "; by others, the negative of W is called "the mutual potential energy of M and M' ."

In many of the later books on this subject, the word

“potential” is never used for the value of the potential function at a point, but is reserved to denote the work required to move a mass from some present position to infinity. If V is the value of the potential function at a point P , at which a mass m is supposed to be concentrated, mV is the *potential of the mass m* . If we could have a unit mass concentrated at a point, the *potential of this mass* and the *value of the potential function at the point* would be numerically identical.

28. Laplace's Equation. We have seen that the value of the potential function and the component in any direction of the attraction at the point P are always finite functions of the space coördinates, whether P is inside, outside, or at the surface of the attracting masses. We have seen also that by differentiating V at any point with respect to any direction we may find the always finite component in that direction of the attraction at the point. It follows that $D_x V$, $D_y V$, $D_z V$ are everywhere finite, and that, in consequence of this, the potential function is everywhere continuous as well as finite.

If P is a point outside of the attracting masses, the quantity under the integral signs in [48], by which $dx'dy'dz'$ is multiplied, cannot be infinite within the limits of integration, and we can find $D_x^2 V$ by differentiating the expression for $D_x V$ under the integral signs.

In this case

$$D_x^2 V = \iiint \frac{3(x' - x)^2 - r^2}{r^5} \rho \, dx' dy' dz', \quad [69]$$

and similarly,

$$D_y^2 V = \iiint \frac{3(y' - y)^2 - r^2}{r^5} \rho \, dx' dy' dz', \quad [70]$$

$$D_z^2 V = \iiint \frac{3(z' - z)^2 - r^2}{r^5} \rho \, dx' dy' dz'. \quad [71]$$

Whence, for all points exterior to the attracting masses,

$$D_x^2 V + D_y^2 V + D_z^2 V = 0. \quad [72]$$

This is Laplace's Equation.

The operator $(D_x^2 + D_y^2 + D_z^2)$ is sometimes denoted by the symbol ∇^2 , so that [72] may be written

$$\nabla^2 V = 0. \quad [73]$$

The potential function, due to every conceivable distribution of matter, must be such that at all points in empty space Laplace's Equation shall be satisfied.

29. The Second Derivatives of the Potential Function are Finite at Points within the Attracting Mass. If the point P lies within the attracting mass, V and $D_x V$ are finite, but the quantity under the integral signs in the expression for $D_x V$ becomes infinite within the limits of integration, and we cannot assume that $D_x^2 V$ may be found by differentiating $D_x V$ under the integral signs. In order to find $D_x^2 V$ under these circumstances, it is convenient to transform the equation for $D_x V$. Let us choose our coördinate axes so as to have all the attracting mass in the first octant, and divide the projection of the contour of this mass on the plane yz into elements $(dy'dz')$. Upon each one of these elements let us erect a right prism, cutting the mass twice or some other even number of times. Consider one of the elements $dy'dz'$ whose corner next the origin has the coördinates $0, y',$ and z' . The prism erected on this element cuts out elements $ds_1, ds_2, ds_3, ds_4, \dots ds_{2n}$ from the surface of the attracting mass and that edge of the prism which is perpendicular to the plane yz at $(0, y', z')$ cuts into the surface at points whose distances from the plane of yz are $a_1, a_3, a_5, \dots a_{2n-1}$, and out of the surface at points whose distances from the same plane are $a_2, a_4, a_6, \dots a_{2n}$. At every one of these points of intersection draw normals towards the interior of the attracting mass, and call the angles which these normals make with the positive direction of the axis of x , $\alpha_1, \alpha_2, \alpha_3, \dots \alpha_{2n}$. It is to be noticed that $\alpha_1, \alpha_3, \alpha_5, \dots \alpha_{2n-1}$ are all acute, and that $\alpha_2, \alpha_4, \alpha_6, \dots \alpha_{2n}$ are all obtuse. The element $dy'dz'$ may be regarded as the common projection of the surface elements

$ds_1, ds_2, ds_3, \dots ds_{2n}$, and, so far as absolute value is concerned, the following equations hold approximately :

$$dy'dz' = ds_1 \cos a_1 = ds_2 \cos a_2 = ds_3 \cos a_3 = \dots = ds_{2n} \cos a_{2n}.$$

But $dy'dz'$, ds_1, ds_2, ds_3 , etc., are all positive areas, and $\cos a_2, \cos a_4, \cos a_6$, etc., are negative, so that, paying attention to signs as well as to absolute values, we have

$$dy'dz' = +ds_1 \cos a_1 = -ds_2 \cos a_2 = +ds_3 \cos a_3 = -ds_4 \cos a_4 = \text{etc.}$$

FIG. 20.

$$D_x \frac{1}{r} = -\frac{1}{r^2} \frac{dx}{dx} \\ = -\frac{1}{r^2} \cdot \frac{x'-x}{r} = -\frac{x'-x}{r^3}$$

Now

$$D_x V = \iiint \frac{\rho(x'-x) dx' dy' dz'}{r^3} = \iint dy' dz' \int \rho D_x' \left(-\frac{1}{r} \right) dx', \quad [74]$$

and in order to find the value of this expression by the use of the prisms just described, we are to cut each one of these prisms into elementary rectangular parallelepipeds by planes parallel to the plane of yz ; we are to multiply the values of every one of these elements which lies within the attracting mass by the value of $\rho D_x' \left(-\frac{1}{r} \right)$ at its corner next the origin [*i.e.*, at (x', y', z')]; and we are to find the limit of the sum of these as dx' is made smaller and smaller. We are then to compute a like expression for each of the other prisms, and to find the limit of the sum of the whole as the bases of the

$$D_x' \left(\text{not } D_x' \right) = \frac{\partial}{\partial x'}$$

prisms are made smaller and smaller and their number correspondingly increased.

Wherever the function $\frac{\rho}{r}$ is a continuous and finite function of x' , we have

$$D_x' \frac{\rho}{r} = \frac{1}{r} D_x' \rho + \rho D_x' \frac{1}{r} = \frac{1}{r} D_x' \rho - \rho D_x' \left(-\frac{1}{r} \right);$$

hence, if the elementary prisms cut the surface of the attracting mass only twice,

$$D_x V = \iint dy' dz' \left[-\frac{\rho}{r} \right]_{x'=a_1}^{x'=a_2} + \iiint \frac{1}{r} D_x' \rho dx' dy' dz'; \quad [75]$$

and, in general,

$$D_x V = \iint dy' dz' \left[\frac{\rho_1}{r_1} - \frac{\rho_2}{r_2} + \frac{\rho_3}{r_3} - \frac{\rho_4}{r_4} + \dots - \frac{\rho_{2n}}{r_{2n}} \right] + \iiint \frac{1}{r} D_x' \rho dx' dy' dz' \quad [76]$$

$$= \lim \sum \left(\frac{\rho_1}{r_1} \cos \alpha_1 ds_1 + \frac{\rho_2}{r_2} \cos \alpha_2 ds_2 + \frac{\rho_3}{r_3} \cos \alpha_3 ds_3 + \dots + \frac{\rho_{2n}}{r_{2n}} \cos \alpha_{2n} ds_{2n} \right) + \iiint \frac{1}{r} D_x' \rho dx' dy' dz', \quad [77]$$

where $\frac{\rho_k}{r_k}$ is the value of the quantity $\frac{\rho}{r}$ at the point where the line $y = y'$, $z = z'$ cuts the surface of the attracting mass for the k th time, counting from the plane yz .

In order to find the value of the limit of the sum which occurs in this expression, it is evident that we may divide the *entire surface* of the attracting mass into elements, multiply the area of each element by the value of $\frac{\rho \cos \alpha}{r}$ at one of its points, and find the limit of the sum formed by adding all these products together; but this is equivalent to the surface integral of $\frac{\rho \cos \alpha}{r}$ taken all over the outside of the attracting mass, so that

$$D_x V = \int \frac{\rho}{r} \cos \alpha ds + \iiint \frac{D_x' \rho}{r} dx' dy' dz', \quad [78]$$

where the first integral is to be taken all over the surface of the attracting mass and the second throughout its volume. This expression for $D_x V$ is in some cases more convenient than that of [48].

We have proved this transformation to be correct, however, only when $\frac{\rho}{r}$ is finite throughout the attracting mass. If P is a point within the mass, $\frac{\rho}{r}$ is infinite at P . In this case surround P by a spherical surface of radius ϵ small enough to make the whole sphere enclosed by this surface lie entirely within the attracting mass. This is possible unless P lies exactly upon the surface of the attracting mass. Shutting out the little sphere, let V_2 be the potential function due to the rest (T_2) of the attracting mass; then, since P is an outside point with regard to T_2 , we have, by [78],

$$D_x V_2 = \int_{\epsilon}^{\rho} \cos \alpha \cdot ds' + \int \frac{\rho}{r} \cos \alpha ds + \iiint \frac{D_x' \rho}{r} dx' dy' dz', \quad [79]$$

where the first integral is to be extended over the spherical surface, which forms a part of the boundary of the attracting

FIG. 21.

mass to which V_2 is due; the second integral is to be taken over all the rest of the bounding surface of the attracting mass; and the triple integral embraces the volume of all the attracting mass which gives rise to V_2 .

As ϵ is made smaller and smaller, V_2 approaches more and more nearly the potential function V , due to all the attracting mass.

In the integral $\int_{\epsilon}^{\rho} \cos \alpha ds'$, $\cos \alpha$ can never be greater than 1 nor less than -1 , so that if $\bar{\rho}$ is the greatest value of ρ on the

and by making P the centre of a system of polar coördinates and transforming all the triple integrals, it is easy to show that the values of $D_x^2 V$, $D_y^2 V$, $D_z^2 V$ here found are finite whether P is within or without the attracting mass. This result* is important.

30. The Derivatives of the Potential Function at the Surface of the Attracting Mass. Let the point P lie on the surface of the attracting mass, or at some other point or surface where ρ is discontinuous. Make P the centre of a sphere of radius ϵ , and call the piece which this sphere cuts out of the attracting mass T_1 and the remainder of this mass T_2 . Let V_1 and V_2 be the potential functions due respectively to T_1 and T_2 , then

$$V = V_1 + V_2, \quad D_x V = D_x V_1 + D_x V_2,$$

and the increment $[\Delta(D_x V)]$ made in $D_x V$ by moving from P to a neighboring point P' , inside T_1 , is equal to the sum of the corresponding increments $[\Delta(D_x V_1)]$ and $[\Delta(D_x V_2)]$ made in $D_x V_1$ and $D_x V_2$.

With reference to the space T_2 , P is an outside point, so that the values at P of the first derivatives of V_2 with respect to x , y , and z are continuous functions of the space coördinates and

$$\lim_{PP' \rightarrow 0} \Delta(D_x V_2) = 0.$$

Let $d\omega$ be the solid angle of an elementary cone whose vertex is at any fixed point O in T_1 used as a centre of coördinates.

FIG. 22.

The element of mass will be $\rho r^2 d\omega dr$. The component in the direction of the axis of x of the attraction at O due to T_1 is the

* Lejeune Dirichlet, *Vorlesungen über die im umgekehrten Verhältniss des Quadrats der Entfernung wirkenden Kräfte*.

Riemann, *Schwere, Electricität, und Magnetismus*.

$$D_x V = \text{force of all } \rho a \text{ on } O_x$$

$$(D_x V_1)_0 = \iint \rho a \cdot d\omega \cdot dr$$

$$< 8\pi\kappa\epsilon$$

limit of the sum taken throughout T_1 of $\frac{\rho r^2 a d\omega dr}{r^2}$, where a is the cosine of the angle which the line joining O with the element in question makes with the axis of x . The difference between the limits of ω is not greater than 4π , and the difference between the limits of r is not greater than 2ϵ . If, then, κ is the greatest value which ρa has in T_1 ,

$$(D_x V_1)_0 < 8\pi\kappa\epsilon.$$

$\begin{matrix} \rho a & d\omega & dr \\ k & 4\pi & 2\epsilon \end{matrix}$

It follows from this that if P' is a point within T_1 so that $PP' < \epsilon$, the change made in $D_x V_1$ by going from P to P' is far less than $16\pi\kappa\epsilon$; but this last quantity can be made as small as we like by making ϵ small enough, so that

$$\lim_{PP' \rightarrow 0} \Delta(D_x V_1) = 0,$$

whence

$$\lim_{PP' \rightarrow 0} \Delta(D_x V) = \lim_{PP' \rightarrow 0} \Delta(D_x V_1) + \lim_{PP' \rightarrow 0} \Delta(D_x V_2) = 0,$$

and $D_x V$ varies continuously in passing through P . In a similar manner, it may be proved that $D_y V$ and $D_z V$ are everywhere, even at places where the density is discontinuous, continuous functions of the space coördinates.

The results of the work of the last two sections are well illustrated by Fig. 17. We might prove, with the help of a transformation due to Clausius,* that the second derivatives of the potential function are finite at all points on the surface of the attracting matter where the curvature is finite, but that these derivatives generally change their values abruptly whenever the point P crosses a surface at which ρ is discontinuous, as at the surface of the attracting masses. The fact, however, that this last is true in the special case of a homogeneous spherical shell suffices to show that we cannot expect the second derivatives of V to have definite values at the boundaries of attracting bodies.

* *Die Potentialfunction und das Potential*, §§ 19-24.

31. Gauss's Theorem. If any closed surface T drawn in a field of force be divided up into a large number of surface elements, and if each one of these elements be multiplied by the component, in the direction of the interior normals of the force of attraction at a point of the element, and if these products be added together, the limit of the sum thus obtained is called the "surface integral of normal attraction over T ."

If any closed surface T be described so as to shut in completely a mass m concentrated at a point, the surface integral of normal attraction due to m , taken over T , is $4\pi m$; and, in general, if any closed surface T be described so as to shut in completely any system of attracting masses M , the surface integral over T of the normal attraction due to M is $4\pi M$.

FIG. 23.

In order to prove this, divide T up into surface elements, and consider one of these ds at Q . The attraction at Q in the direction QO , due to the mass m concentrated at O , is $\frac{m}{QO^2} = \frac{m}{r^2}$.

The component of this in the direction of the interior normal is $\frac{m}{r^2} \cos \alpha$, and the contribution which ds yields to the sum whose

limit is the surface integral required is $\frac{m \cos \alpha ds}{r^2}$. Connect

every point of the perimeter of ds with O by a straight line, thus forming a cone of such size as to cut out of a spherical surface of unit radius drawn about O an element $d\omega$, say. If we draw about O a sphere of radius $r = OQ$, the cone will intercept on its surface an element equal to $r^2 \cdot d\omega$. This element is the

projection on the spherical surface of ds ; hence $ds \cos \alpha = r^2 d\omega$, approximately, and the contribution of the element ds to our surface integral is $m d\omega$. But an elementary cone may cut the surface more than once; indeed, any odd number of times. Consider such a cone, one element of which cuts the surface thrice in S_1 , S_2 , and S_3 . Let OS_1 , OS_2 , and OS_3 be called r_1 , r_2 , and r_3 respectively, and let the surface elements cut out of T by the cone be ds_1 , ds_2 , and ds_3 , and the angles between the line S_3O and the interior normals to T at S_1 , S_2 , and S_3 be α_1 , α_2 , α_3 . It is to be noticed that when the cone cuts out of T , the corresponding angle is acute, and that when it cuts in, the corresponding angle is obtuse. α_1 and α_3 are acute, and α_2 obtuse. If we draw about O three spherical surfaces with radii r_1 , r_2 , and r_3 respectively, the cone will cut out of these the elements $r_1^2 d\omega$, $r_2^2 d\omega$, and $r_3^2 d\omega$. In absolute size, $ds_1 = r_1^2 d\omega \sec \alpha_1$, $ds_2 = r_2^2 d\omega \sec \alpha_2$, and $ds_3 = r_3^2 d\omega \sec \alpha_3$, approximately, but ds_2 and $r^2 d\omega$ are both positive, being areas, and $\sec \alpha_2$ is negative. Taking account of sign, then, $ds_2 = -r^2 d\omega \sec \alpha_2$, and the cone's three elements yield to the surface integral of normal attraction the quantity

$$m \left(\frac{ds_1 \cos \alpha_1}{r_1^2} + \frac{ds_2 \cos \alpha_2}{r_2^2} + \frac{ds_3 \cos \alpha_3}{r_3^2} \right) = m(d\omega - d\omega + d\omega) = m d\omega.$$

However many times the cone cuts T , it will yield $m d\omega$ to the surface integral required: all such elementary cones will yield then $m \sum d\omega = m 4\pi$ if T is closed, and, in general, $m\Theta$, when Θ is the solid angle which T subtends at O .

If, instead of a mass concentrated at a point, we have any distribution of masses, we may divide these into elements, and apply to each element the theorem just proved; hence our general statement.

If from a point O without a closed surface T an elementary cone be drawn, the cone, if it cuts T at all, will cut it an even number of times. Using the notation just explained, the contribution which any such cone will yield to the surface integral taken over T of a mass m concentrated at O is

$$\begin{aligned}
 m \left(\frac{ds_1 \cos a_1}{r_1^2} + \frac{ds_2 \cos a_2}{r_2^2} + \frac{ds_3 \cos a_3}{r_3^2} + \frac{ds_4 \cos a_4}{r_4^2} + \dots \right) \\
 = m(-d\omega + d\omega - d\omega + d\omega - \dots) = m \cdot 0 = 0,
 \end{aligned}$$

and the surface integral over any closed surface of the normal attraction due to any system of outside masses is zero.

The results proved above may be put together and stated in the form of a

THEOREM DUE TO GAUSS.

If there be any distribution of matter partly within and partly without a closed surface T , and if M be the sum of the masses which T encloses, and M' the sum of the masses outside T , the surface integral over T of the normal attraction N toward the interior, due to both M and M' , is equal to $4\pi M$. If V be the potential function due to both M and M' , we have

$$\int N ds = \int D_n V \cdot ds = 4\pi M.$$

It is easy to see that if a mass M be supposed concentrated on the surface of any closed surface T whose curvature is everywhere finite, the surface integral of normal attraction taken over T will be $2\pi M$; for all the elementary cones which can be drawn from a point P in the surface so as to cut T once or some other odd number of times lie on one side of the tangent plane at the point, and intercept just half the surface of the sphere of unit radius whose centre is P .

From Gauss's Theorem it follows immediately that at some parts of a closed surface situated in a field of force, but enclosing none of the attracting mass, the normal component of the resultant attraction must act towards the interior of the surface and at some parts toward the exterior, for otherwise the limit of the sum of the intrinsically positive elements of the surface, each one multiplied by the component in the direction of the interior normal of the attraction at one of its own points, could not be zero. In other words, the potential function, whose rate of change measures the attraction, must at some

parts of the surface increase and at others decrease in the direction of the interior normal.

From this it follows that the potential function cannot have a maximum or a minimum value at a point in empty space; for if at such a point Q the potential function had a maximum value, we could surround Q by a small closed surface, at every point of which the potential function would increase in the direction of the interior normal, and this would be inconsistent with the fact that the surface integral of normal attraction taken over the surface, which would contain no matter, must be zero. Similarly it may be shown that the potential function cannot have a minimum value at a point in empty space.

If the potential function be constant over a closed surface which contains none of the attracting mass, it has the same value throughout the interior; for if this were not the case, some point or region Q within T would have a value greater or less than the surrounding region, and we could enclose Q by a closed surface to which we could apply the course of reasoning just used to show that V cannot attain a maximum value at a point in empty space.

32. Tubes of Force. A line which cuts orthogonally the different members of the system of equipotential surfaces corresponding to any distribution of matter is called a "line of force," since its direction at each point of its course shows the direction of the resultant force at the point. If through all points of the contour of a portion of an equipotential surface lines of force be drawn, these lines lie on a surface called a

FIG. 24.

"tube of force." We may easily apply Gauss's Theorem to a space cut out and bounded by a portion of a tube of force and two equipotential surfaces; for the sides of the tube do not con-

tribute anything to the surface integral of normal attraction, and the resultant force is all normal at points in the equipotential surfaces. If ω and ω' are the areas of the sections of a tube of force made by two equipotential surfaces, and if F and F' are the average interior forces on ω and ω' , we have

$$F\omega + F'\omega' = 0 \quad [87]$$

if the tube encloses empty space, and

$$F\omega + F'\omega' = 4\pi m \quad [88]$$

when the tube encloses a mass m of attracting matter.

33. Spherical Distributions. In the case of a distribution ^{of attracting matter} about a point in spherical shells, so that the density is a function of the distance from this point only, the lines of force are straight lines whose directions all pass through the central point. Every tube of force is conical, and the areas cut out of different equipotential surfaces by a given tube of force are proportional to the square of the distance from the centre.

Consider a tube of force which intercepts an area ψ from a spherical surface of unit radius drawn with O as a centre, and apply Gauss's Theorem to a box cut out of this tube by two equipotential surfaces of radii r and $(r + \Delta r)$ respectively.

FIG. 25.

Let AOB (Fig. 25) be a section of the tube in question. The area of the portion of spherical surface ω which is represented in section at ad is $r^2\psi$, and the area of that at bc is $(r + \Delta r)^2\psi$. If the average force acting on ω toward the inside of the box is F , the average force acting on ω' toward the inside of the box will be $-(F + \Delta_r F)$, and the surface integral of normal attraction taken all over the outside of the box is

$$Fr^2\psi - (F + \Delta_r F)(r + \Delta r)^2\psi = -\psi \cdot \Delta_r(F \cdot r^2). \quad [89]$$

If the tube of force which we have been considering be extended far enough, it will cut all the concentric layers of matter, traverse all the empty regions between the layers, if there are such, and finally emerge into outside space.

If we choose r so that the box shall contain no matter, the surface integral taken over the box must be zero.

In this case,

$$-\psi \Delta_r (Fr^2) = 0,$$

therefore,
$$F = \frac{c}{r^2}, \quad [90]$$

and
$$V = -\frac{c}{r} + \mu. \quad [91]$$

From this it follows that in a region of empty space, either included between the two members of a system of concentric spherical shells of density depending only upon the distance from the centre, or outside the whole system, the force of attraction at different points varies inversely as the squares of the distances of these points from the centre.

Suppose that the box ($abcd$) lies in a shell whose density is constant; then the surface integral of normal attraction taken over the box is equal to 4π times the matter within the box. In this case the quantity of matter inside the box is

$$\rho \frac{4}{3} \pi [(r + \Delta r)^3 - r^3] \frac{\psi}{4\pi} \text{ or } \rho \psi r^2 \Delta r + \epsilon,$$

where ϵ is an infinitesimal of an order higher than the first. Therefore,

$$-\psi \Delta_r (Fr^2) = 4\pi (\rho \psi r^2 \Delta r + \epsilon),$$

or
$$\lim_{\Delta r \rightarrow 0} \frac{\Delta_r (Fr^2)}{\Delta r} = -4\pi \rho r^2,$$

whence
$$F = -\frac{4\pi \rho r}{3} + \frac{c}{r^2}, \quad [92]$$

and
$$V = -\frac{c}{r} - \frac{2}{3} \pi \rho r^2 + \mu. \quad [93]$$

If the box lies in a shell whose density is inversely proportional to the distance from the centre, we shall have

$$\lim_{\Delta r \rightarrow 0} \frac{\Delta_r (Fr^2)}{\Delta r} = -4\pi \left(\frac{\lambda}{r}\right) r^2, \quad [94]$$

whence
$$F = -2\pi\lambda + \frac{c}{r^2}, \quad [95]$$

and
$$V = -\frac{c}{r} - 2\pi\lambda r + \mu. \quad [96]$$

In general, if the box lies in a shell whose density is $f(r)$, we shall have

$$\lim_{\Delta r \rightarrow 0} \frac{\Delta_r (Fr^2)}{\Delta r} = -4\pi f(r) r^2, \quad [97]$$

whence
$$F = \frac{c}{r^2} - \frac{4\pi}{r^2} \int f(r) r^2 \cdot dr. \quad [98]$$

In order to learn how to use the results just obtained to determine the force of attraction at any point due to a given spherical distribution, let us consider the simple case of a single shell, of radii 4 and 5, and of density $[\lambda r]$ proportional to the distance from the centre.

At points within the cavity enclosed by the shell we must have, according to [90] and [91],

$$F = \frac{c}{r^2} \quad \text{and} \quad V = -\frac{c}{r} + \mu; \quad c = 0$$

But the force is evidently zero at the centre of the shell, where r is zero, so that c must be zero everywhere within the cavity, and there is no resultant force at any point in the region. The value, at the centre, of the potential function due to the shell is evidently

$$\mu = \int_4^5 4\pi\lambda r^2 dr = \frac{244\pi\lambda}{3}, \quad [99]$$

and it has the same value at all other points in the cavity.

In the shell itself it is easy to see that we must have at all points,

$$F = \frac{c'}{r^2} - \pi\lambda r^2 \quad \text{and} \quad V = -\frac{c'}{r} - \frac{\pi\lambda r^3}{3} + \mu'. \quad [100]$$

In order to determine the constants in this equation, we may make use of the fact that F and V are everywhere continuous functions of the space coördinates, so that the values of F and V obtained by putting $r = 4$, the inner radius of the shell, in [100], must be the same as those obtained by making $r = 4$ in the expressions which give the values of F and V for the cavity enclosed by the shell. This gives us

$$c' = 0 \quad c' = 256 \pi \lambda \quad \text{and} \quad \mu' = \frac{500 \pi \lambda}{3},$$

so that for points within the mass of the shell we have

$$F = \frac{256 \pi \lambda}{r^2} - \pi \lambda r^2, \quad [101]$$

and
$$V = -\frac{256 \pi \lambda}{r} - \frac{\pi \lambda r^3}{3} + \frac{500 \pi \lambda}{3}. \quad [102]$$

For points without the shell we have the same general expressions for F and V as for points within the cavity enclosed by the shell, namely,

$$F = \frac{k}{r^2} \quad \text{and} \quad V = -\frac{k}{r} + m, \quad [103]$$

but the constants are different for the two regions.

Keeping in mind the fact that F and V are continuous, it is easy to see that we must get the same result at the boundary of the shell, where $r = 5$, whether we use [103], or [101] and [102].

This gives

$$k = -369 \pi \lambda \quad \text{and} \quad m = 0;$$

so that for all points outside the shell we have

$$F = -\frac{369 \pi \lambda}{r^2}, \quad [104]$$

and
$$V = \frac{369 \pi \lambda}{r}. \quad [105]$$

These last results agree with the statements made in Section 13, for the mass of the shell is $369 \pi \lambda$.

The values, at every point in space, of the potential function and of the attraction due to any spherical distribution may be

Try this for distribution given in example 9, p. 68.

$$\begin{aligned} F &= -\frac{4}{3} \pi \rho r \dots r < 1 \\ &= -\frac{4}{3} \pi \frac{\rho}{r} \dots 1 < r < \\ &= -\frac{4}{3} \pi \rho r - \frac{28}{3} \frac{\pi \rho}{r} \dots r > 1 \\ &= -\infty \pi \rho \dots r > \end{aligned}$$

For a finite distribⁿ we can begin from outside & come
 in. i.e. get constants by considering that $V = 0$ at ∞ .

found by determining, first, with the aid of Gauss's Theorem, the general expressions for F and V in the several regions; then the constants for the innermost region, remembering that there is no resultant attraction at the centre of the system; and finally, in succession (moving from within outwards), the constants for the other regions, from a consideration of the fact that no abrupt change in the values of either F or V is made by crossing the common boundary of two regions.

This method of treating problems is of great practical importance.

34. Cylindrical Distributions. In the case of a cylindrical distribution about an axis, where the density is a function of the distance from the axis only, the equipotential surfaces are concentric cylinders of revolution; the lines of force are straight lines perpendicular to the axis; and every tube of force is a wedge.

If we apply Gauss's Theorem to a box shut in between two equipotential surfaces of radii r and $r + \Delta r$, two planes perpendicular to the axis, and two planes passing through the axis,

FIG. 26.

we have, if ψ is the area of the piece cut out of the cylindrical surface of unit radius by our tube of force,

$$\omega = r \cdot \psi, \quad \omega' = (r + \Delta r) \cdot \psi,$$

and for the surface integral of normal attraction taken over the box,

$$F\omega + F'\omega' = -\psi \cdot \Delta_r(r \cdot F). \quad [106]$$

If our box is in empty space,

$$\Delta_r(r \cdot F) = 0,$$

so that

$$F = \frac{c}{r} \quad \text{and} \quad V = c \log r + \mu. \quad [107]$$

If the box is within a shell of constant density ρ ,

$$-\psi \cdot \Delta_r(r \cdot F) = 4\pi\psi\rho r \Delta r,$$

so that $F = \frac{c}{r} - 2\pi\rho r$ and $V = c \log r - \pi\rho r^2 + \mu.$ [108]

35. Poisson's Equation. Let us now apply Gauss's Theorem to the case where our closed surface is that of an element of volume of an attracting mass in which ρ is either constant or a continuous function of the space coördinates. We will consider three cases, using first rectangular coördinates, then cylinder coördinates, and finally spherical coördinates.

FIG. 27.

I. In the first case, our element is a rectangular parallelepiped (Fig. 27). Perpendicular to the axis of x are two equal surfaces of area $\Delta y \cdot \Delta z$, one at a distance x from the plane yz , and one at a distance $x + \Delta x$ from the same plane. The average force perpendicular to a plane area of size $\Delta y \Delta z$, parallel to the plane yz , and with edges parallel to the axes of y and z , is evidently some function of the coördinates of the corner of the element nearest the origin.

That is, if $P = (x, y, z)$, the average force on PP_4 parallel to the axis of x is $X = f(x, y, z)$, and the average force on P_1P_7 in the same direction is $f(x + \Delta x, y, z) = X + \Delta_x X$, so that PP_4 and P_1P_7 yield towards the surface integral of interior-normal attraction taken over the element, the quantity $-\Delta x \Delta y \Delta z \cdot \frac{\Delta_x X}{\Delta x}$. Similarly, the other two pairs of elementary surfaces yield

$-\Delta x \Delta y \Delta z \frac{\Delta_y Y}{\Delta y}$ and $-\Delta x \Delta y \Delta z \frac{\Delta_z Z}{\Delta z}$, and, if ρ_0 is the average density of the matter enclosed by the box, we have

$$-\Delta x \Delta y \Delta z \left[\frac{\Delta_x X}{\Delta x} + \frac{\Delta_y Y}{\Delta y} + \frac{\Delta_z Z}{\Delta z} \right] = 4\pi\rho_0 \Delta x \Delta y \Delta z. \quad [109]$$

This equation is true whatever the size of the element $\Delta x \Delta y \Delta z$. If this element is made smaller and smaller, the average normal force $[X]$ on PP_4 approaches in value the force $[D_x V]$ at P in the direction of the axis of x ; Y and Z approach respectively the limits $D_y V$ and $D_z V$; and ρ_0 approaches as its limit the actual density $[\rho]$ at P .

Taking the limits of both sides of [109], after dividing by $\Delta x \Delta y \Delta z$, we have

$$D_x^2 V + D_y^2 V + D_z^2 V = -4\pi\rho,$$

or

$$\nabla^2 V = -4\pi\rho, \quad [110]$$

which is Poisson's Equation. The potential function due to any conceivable distribution of attracting matter must be such that at all points within the attracting mass this equation shall be satisfied.

For points in empty space $\rho = 0$, and Poisson's Equation degenerates to Laplace's Equation.

II. In the case of cylindrical coördinates, the element of volume (Fig. 28) is bounded by two cylindrical surfaces of revo-

FIG. 28.

lution having the axis of z as their common axis and radii r and $r + \Delta r$, two planes perpendicular to this axis and distant Δz

from each other, and two planes passing through the axis and forming with each other the diedral angle $\Delta\theta$.

Call R , Θ , and Z the average normal forces upon the elementary planes PP_6 , PP_2 , and PP_3 respectively, then the surface integral of normal attraction over the volume element will be

$$-\Delta\theta\Delta z\Delta_r(r \cdot R) - \Delta r\Delta z\Delta_\theta\Theta - \Delta\theta[r\Delta r + \frac{1}{2}(\Delta r)^2]\Delta_z Z = 4\pi\rho_0 (\text{vol. of box}); \quad [111]$$

whence, approximately,

$$\frac{1}{r} \frac{\Delta_r(rR)}{\Delta r} + \frac{1}{r} \frac{\Delta_\theta\Theta}{\Delta\theta} + \frac{\Delta_z Z}{\Delta z} = -4\pi\rho_0 \frac{\text{vol. of box.}}{r\Delta r\Delta\theta\Delta z}. \quad [112]$$

The force at P in direction PP_5 is $D_r V$, in direction PP_4 is $D_z V$, and perpendicular to LP in the plane PLP_1 is $\frac{1}{r} \cdot D_\theta V$, so that if the box is made smaller and smaller, our equation approaches the form

$$\frac{1}{r} D_r(r \cdot D_r V) + \frac{1}{r^2} D_\theta^2 V + D_z^2 V = -4\pi\rho. \quad [113]$$

$\frac{\partial v}{\partial s} = \frac{\partial v}{r \partial \theta}$
 $= \frac{1}{r} D_\theta v$

FIG. 29.

III. In the case of spherical coördinates, the volume element is of the shape shown in Fig. 29. Let $OP=r$, $ZOP=\theta$, and

denote by ϕ the dihedral angle between the planes ZOP and ZOX . Denote by R , Θ , and Φ the average normal forces on the faces PP_6 , PP_3 , and PP_2 respectively; then the surface integral of normal attraction over the elementary box is approximately

$$\begin{aligned} & -\sin\theta\Delta\theta\Delta\phi\cdot\Delta_r(r^2R) - r\Delta\theta\Delta r\Delta\phi\Phi - r\Delta\phi\Delta r\cdot\Delta_\theta(\sin\theta\cdot\Theta) \\ & = 4\pi\rho_0\cdot(\text{vol. of box}); \end{aligned} \quad [114]$$

$$\begin{aligned} \text{whence } & \frac{1}{r^2}\cdot\frac{\Delta_r(r^2R)}{\Delta r} + \frac{1}{r\sin\theta}\cdot\frac{\Delta_\phi\Phi}{\Delta\phi} + \frac{1}{r\sin\theta}\cdot\frac{\Delta_\theta(\sin\theta\cdot\Theta)}{\Delta\theta} \\ & = -4\pi\rho_0\cdot\frac{\text{vol. of box}}{r^2\sin\theta\Delta r\Delta\theta\Delta\phi}. \end{aligned} \quad [115]$$

The force at P in the direction PP_5 is D_rV , in the direction PP_1 is $\frac{1}{r\sin\theta}\cdot D_\phi V$, and in the direction PP_4 is $\frac{1}{r}\cdot D_\theta V$; therefore, as the element of volume is made smaller and smaller, our equation approaches the form

$$\begin{aligned} & \sin\theta\cdot D_r(r^2D_rV) + \frac{D_\phi^2V}{\sin\theta} + D_\theta(\sin\theta\cdot D_\theta V) \\ & = -4\pi\rho r^2\sin\theta. \end{aligned} \quad [116]$$

This equation, as well as that for cylinder coördinates, might have been obtained by transformation from the equation in rectangular coördinates.

36. Poisson's Equation in the Integral Form. In [109] X may be regarded as a function of $x, y, z, \Delta y$, and Δz , which approaches D_xV as a limit when Δy and Δz are made to approach zero, and it may not be evident that the limit, when $\Delta x, \Delta y$, and Δz are together made to approach zero, of the fraction $\frac{\Delta_x X}{\Delta x}$ is D_x^2V . For this reason it is worth while to establish Poisson's Equation by another method.

It is shown in Section 29 that the volume integral of the quantity $-D_x\left(\frac{\rho}{r}\right)$, taken throughout a certain region, is the sur-

face integral of $\frac{\rho}{r} \cos \alpha$ taken all over the surface which bounds the region. In this proof we might substitute for $\frac{\rho}{r}$ any other function of the three space coördinates which throughout the region is finite, continuous, and single-valued, and state the results in the shape of the following theorem :

If T is any closed surface and U a function of $x, y,$ and z which for every point inside T has a finite, definite value which changes continuously in moving to a neighboring point, then

$$\iiint D_x U \cdot dx dy dz = - \int U \cos \alpha ds, \quad [117]$$

$$\iiint D_y U \cdot dx dy dz = - \int U \cos \beta ds, \quad [118]$$

and
$$\iiint D_z U \cdot dx dy dz = - \int U \cos \gamma ds, \quad [119]$$

where $\alpha, \beta,$ and γ are the angles made by the interior normals at the various points of the surface with the positive direction of the coördinate axes, and where the sinister integrals are to be extended all through the space enclosed by T , and the dexter integrals all over the bounding surface.

If we apply this theorem to an imaginary closed surface which shuts in any attracting mass of density either uniform or variable, and if for U in [117], [118], and [119] we use respectively $D_x V, D_y V,$ and $D_z V,$ and add the resulting equations together, we shall have

$$\begin{aligned} & \iiint (D_x^2 V + D_y^2 V + D_z^2 V) dx dy dz \\ &= - \int (D_x V \cos \alpha + D_y V \cos \beta + D_z V \cos \gamma) ds. \quad [120] \end{aligned}$$

The integral in the second member of this equation is evidently (see [56]) the surface integral of normal attraction taken over our imaginary closed surface, and this by Gauss's Theorem is equal to 4π times the quantity of matter inside the surface, so that

$$\begin{aligned} \iiint (D_x^2 V + D_y^2 V + D_z^2 V) dx dy dz \\ = -4\pi \iiint \rho dx dy dz. \end{aligned} \quad [121]$$

Since this equation is true whatever the form of the closed surface, we must have at every point

$$D_x^2 V + D_y^2 V + D_z^2 V = -4\pi\rho.$$

For if throughout any region $\nabla^2 V$ were greater than $-4\pi\rho$, we might take the boundary of this region as our imaginary surface. In this case every term in the sum whose limit gives the sinister of [121] would be greater than the corresponding term in the dexter, so that the equation would not be true. Similar reasoning shuts out the possibility of $\nabla^2 V$'s being less than $-4\pi\rho$.

37. The Average Value of the Potential Function on a Spherical Surface. If, in a field of force due to a mass m concentrated at a point P , we imagine a spherical surface to be drawn so as to exclude P , the surface integral taken over this surface of the value of the potential function due to m is equal to the area of the surface multiplied by the value of the potential function at the centre of the sphere.

To prove this, let the radius of the sphere be a and the distance $[OP]$ of P from its centre c . Take the centre of the sphere for origin and the line OP for the axis of x . Divide the surface of the sphere into zones by means of a series of planes cutting the axis of x perpendicularly at intervals of Δx . The area of each one of these zones is $2\pi a dx$, so that the surface integral of $\frac{m}{r}$ is

$$\int_{-a}^{+a} \frac{m 2\pi a dx}{\sqrt{a^2 + c^2 - 2cx}} = - \left[\frac{2\pi m a \sqrt{a^2 + c^2 - 2cx}}{c} \right]_{-a}^{+a}$$

and the value of this, since the radical represents a positive quantity, is $\frac{4\pi a^2 m}{c}$, which proves the proposition.

The surface integral of the potential function taken over the sphere divided by the area of the sphere is often called "the average value of the potential function on the spherical surface."

If we have any distribution of attracting matter, we may divide it into elements, apply the theorem just proved to each of these elements, and, since the potential function due to the whole distribution is the sum of those due to its parts, assert that:

The average value on a spherical surface of the potential function due to any distribution of matter entirely outside the sphere is equal to the value of the potential function at the centre of the sphere.

It follows, from this theorem, that if the potential function is constant within any closed surface S drawn in a region T , which contains no matter, so as to shut in a part of that region, it will have the same value in those parts of T which lie outside S . For, if the values of the potential function at points in empty space just outside S were different from the value inside, it would always be possible to draw a sphere enclosing no matter whose centre should be inside S , and which outside S should include only such points as were all at either higher or lower potential than the space inside S ; but in this case the value of the potential function at the centre of the sphere would not be the average of its values over its surface.

The value of the potential function cannot be constant in unlimited empty space surrounding an attracting mass M , for, if it were, we could surround the mass by a surface over which the surface integral of normal attraction would be zero instead of $4\pi M$.

The average value on a spherical surface of the potential function $[V]$, due to any distribution $[M]$ of attracting matter wholly within the surface, is the same as if M were concentrated at the centre O of the space which the surface encloses. For the average values $[V_0$ and $V_0 + \Delta, V_0]$ of V on concentric spherical surfaces of radii r and $r + \Delta r$ may be written

$$\frac{m}{c}$$

$\frac{1}{4\pi r^2} \int V ds$ (or $\frac{1}{4\pi} \int V d\omega$, if $d\omega$ is the solid angle of an elementary cone with vertex at O , which intercepts the element ds from the surface of a sphere of radius r), and $\frac{1}{4\pi} \int (V + \Delta_r V) d\omega$;

whence
$$\Delta_r V_0 = \frac{1}{4\pi} \int \Delta_r V \cdot d\omega,$$

and
$$D_r V_0 = \frac{1}{4\pi} \int D_r V \cdot d\omega.$$

Now $-\int D_r V \cdot \alpha^2 d\omega$ is the integral of normal attraction taken over the spherical surface, whence, by Gauss's Theorem,

$$D_r V_0 = -\frac{4\pi M}{4\pi r^2}, \quad \text{and} \quad V_0 = \frac{M}{r} + 0,$$

since $V_0 = 0$, for $r = \infty$.

38. The Equilibrium of Fluids at Rest under the Action of Given Forces. Elementary principles of Hydrostatics teach us that when an incompressible fluid is at rest under the action of any system of applied forces, the hydrostatic pressure p at the point (x, y, z) must satisfy the differential equation

$$dp = \rho(Xdx + Ydy + Zdz), \quad [122]$$

where X , Y , and Z are the values at that point of the force applied per unit of mass to urge the liquid in directions parallel to the coördinate axes.

For, if we consider an element of the liquid $[\Delta x \Delta y \Delta z]$ (Fig. 27) whose average density is ρ_0 and whose corner next the origin has the coördinates (x, y, z) , and if we denote by p_x the average pressure per unit surface on the face $PP_2P_4P_3$, by $p_x + \Delta_x p_x$ the average pressure on the face $P_1P_5P_7P_6$, and by X_0 the average applied force per unit of mass which tends to move the element in a direction parallel to the axis of x , we have, since the element is at rest,

$$p_x \Delta y \Delta z + \rho_0 X_0 \Delta x \Delta y \Delta z = (p_x + \Delta_x p_x) \Delta y \Delta z,$$

or
$$\rho_0 X_0 = \frac{\Delta_x p_x}{\Delta x}.$$

If the element be made smaller and smaller, the first side of the equation approaches the limit ρX , and the second side the limit $D_x p$, where p is the hydrostatic pressure, equal in all directions, at the point P .

This gives us
$$D_x p = \rho X. \quad [123]$$

In a similar manner, we may prove that

$$D_y p = \rho Y,$$

and

$$D_z p = \rho Z;$$

whence

$$\begin{aligned} dp &= D_x p dx + D_y p dy + D_z p dz \\ &= \rho(X dx + Y dy + Z dz). \end{aligned}$$

If in any case of a liquid at rest the only external force applied to each particle is the attraction due to some outside mass, or to the other particles of the liquid, or to both together, X , Y , and Z are the partial derivatives with regard to x , y , and z of a single function V , and we may write our general equation in the form

$$dp = \rho(D_x V \cdot dx + D_y V \cdot dy + D_z V \cdot dz) = \rho \cdot dV,$$

whence, if ρ is constant,

$$p = \rho V + \text{const.}, \quad [124]$$

and the surfaces of equal hydrostatic pressure are also equipotential surfaces.

According to this, the free bounding surfaces of a liquid at rest under the action of gravitation only are equipotential.

EXAMPLES.

- ^{32,} _{t part} 1. Prove that a particle cannot be in stable equilibrium under the attraction of any system of masses. [Earnshaw.] *(Munich Art. 3)*
2. Prove that the number of ergs required to move to infinity a mass of one gramme concentrated at a point P is the value of the potential function at P divided by about 15220000. *1 dyne in alt. unit*
3. Prove that if all the attracting mass lies within an equipotential surface S on which $V = C$, then in all space outside S the value of the potential function lies between C and 0.

4. The source of the Mississippi River is nearer the centre of the earth than the mouth is. What can be inferred from this about the slope of level surfaces on the earth?

5. If in [59] x be made equal to zero, V becomes infinite. How can you reconcile this with what is said in the first part of Section 22?

6. Are all solutions of Laplace's Equation possible values of the potential function in empty space due to distributions of matter? Assume some particular solution of this equation which will serve as the potential function due to a possible distribution and show what this distribution is.

7. If the lines of force which traverse a certain region are parallel, what may be inferred about the intensity of the force within the region?

8. The path of a material particle starting from rest at a point P and moving under the action of the attraction of a given mass M is not in general the line of force due to M which passes through P . Discuss this statement, and consider separately cases where the lines of force are straight and where they are curved.

9. Draw a figure corresponding to Figure 17 for the case of a uniform sphere of unit radius surrounded by a concentric spherical shell of radii 2 and 3 respectively.

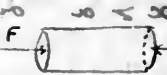

10. Draw with the aid of compasses traces of four of the equipotential surfaces due to two homogeneous infinite cylinders of equal density whose axes are parallel and at a distance of 5 inches apart, assuming the radius of one of the cylinders to be 1 inch and that of the other to be 2 inches.

11. Draw with the aid of compasses meridian sections of four of the equipotential surfaces due to two small homogeneous spheres of mass m and $2m$ respectively, whose centres are 4 inches apart. Can equipotential surfaces be drawn so as to lie wholly or partly within one of the spheres? What value of the potential function gives an equipotential surface shaped like the figure 8? Show that the value of the resultant force at the point where this curve crosses itself is zero.

4. The equip. lines are not parallel to the surface of the earth, but are roughly prolate spheroids with earth's axis as their principal axis.

5. The formula is obtained on the supposition that the section of the wire is inf^{ly} small compared to x . Hence this limiting case is not included in the expression [57]. See Minipin p. 244 (middle) p. 279 Ex. 2.

6. Normals $V = \dots$
 (define) But when $x = \infty$, $V = \dots$ p. 282, Ex.
 Very hard to get distrib^{ns} besides ordinary ones.

7. $F \int ds + F' \int ds = 0 = F$

 Tube of force $\approx V \cdot F = F' \cdot V$ (Gauss).

8. Lines of force straight in spherical distribⁿ about a point. If line of force str, path in it.

A material particle will not describe a certain curved path unless it has two accelerations
 (m) $\frac{dv}{dt}$ along tangent
 (m) $\frac{v^2}{r}$ along normal

Usually this is not the case: particle leaves the curve of force on acctⁿ of inertia -

where $V = \dots$
 here $C' = \infty$, but this does not prevent us getting equipot. surfaces. We are interested chief in V & the D of a const. = 0
 in a pt. in equipot. space

(inclusion) $V + V' = V$
 $[A + A + D + D + r \log r + \dots] \dots =$
 $\dots = C$ const

or for an present case $r^2 = \text{const}$
 $\dots = C$

10. Consider a single cylinder of radius a . The force depends only on $f(r)$ i.e. we have a cylindrical distribution.

∴ $F = \frac{c}{r}$ (Art. 34) outside mass. The source of the Mississippi River is near the centre of the earth and $F = -2\pi\rho r$ can be inferred from this.

Now considering what $r = 0$? F being continuous if in [59] ρ be made equal to zero, V becomes infinite. How can $F = 0$ reconcile with $V = \infty$ (force at centre)? Section 22?

$F = -2\pi\rho r$ for $r < a$ (inside)
 $F = -\frac{2\pi\rho a^2}{r}$ for $r > a$ (outside)
 the potential function $V = -2\pi\rho a^2 \log r$ due to distribution outside matter? (A) Are some particular solutions of the equation $\text{Div } \nabla V = F$ possible distribution and how what the distribution is.

1st inside $\text{Div } \nabla V = -2\pi\rho r$ a certain region; parallel, what may be inferred about the intensity of force within the region?
 $V = -\pi\rho r^2 + C_1$ ($r < a$)

2nd outside of $\text{Div } \nabla V = -\frac{2\pi\rho a^2}{r}$ starting from rest at a point P and moving under the action of the attraction of a given mass M is not in general the line of force due to M which passes through P . Discuss this statement, and consider separately cases where considering that when $r = a$ there are equal curves.
 $V = -2\pi\rho a^2 \log r + C_2$ ($r > a$)

a uniform sphere $C_2 = 2\pi\rho a^2(2 \log a - 1) + C_1$ spheric potential of figure 2 and 3 respectively.

Hence $V = -2\pi\rho a^2 \log r + 2\pi\rho a^2(2 \log a - 1) + C_1$ ($r > a$)
 equipotential surfaces due to two homogeneous or infinite cylinders of equal density whose axes are parallel and at a distance of 5 inches apart, assuming the radius of one of the cylinders to be 2 inches. We are interested chiefly in the equipotential surfaces.

in $\text{Div } \nabla V$ with the Div of a constant = 0 plan sections of four of the equipotential surfaces due to two small homogeneous spheres of mass m and $2m$ respectively, whose centres are 4 inches apart. Can you plot (the two cylinders) as to lie wholly or partly within one of the spheres? What value of the potential function $= -2\pi\rho [a^2 \log r_1 + b^2 \log r_2 + C_1 + C_2 + D_1 + D_2]$ like the figure 8? Show that the value of the resultant force at the point where $r = ca$ (on at itself) is zero.

Run constants over to other side r

$$a^2 \log r_1 + b^2 \log r_2 = C$$

$$\text{or for our present case } r_1 r_2 = \text{const.}^4$$

The surfaces are shaped as in figure :

12. A sphere of radius 3 inches and of constant density μ is surrounded by a spherical shell concentric with it of radii 4 inches and 5 inches and of density μr , where r is the distance from the centre. Compute the values of the attraction and of the potential function at all points in space and draw curves to illustrate the fact. (Compare *D, Mechanics*, p. 282, Ex. 7) and that $D_r V$ is discontinuous at certain points.

11. 13. A very long cylinder of radius 1 inch and of constant density μ is surrounded by a cylindrical shell coaxial with it and of radii 6 inches and 8 inches. "8" shaped this surface inverse square proportional to the square of the distance from axis, and G a point 8 inches from axis. Use the method of Gauss to find the force at G due to 1. balance that due to 2.

Let $r_1 + r_2 = 4$ inches
 its
 of $\frac{1}{r_1^2} = \frac{2}{r_2^2} = \frac{2}{(4-r_1)^2}$

to find the $r_1 = 1.64$
 $r_2 = 2.36$

15. Are there any other cases like these in which the density of the attracting matter depends only upon the distance from a plane, from an axis, or from a central point, where surfaces of equal force are also equipotential surfaces? Prove your assertion.

16. Prove that if a mass M_1 be divided up into elements, and if each one of these elements be multiplied by its value at one of its own points of the potential function V , due to another mass M_2 , the limit of the sum of these multiplied members will be equal to the limit of the sum over M_2 of the product of the masses of its elements by the corresponding values of the potential function due to M_1 at the same points.

$$\int (M_1 dM_1 =) M_1 M_2$$

where the surface integral is to embrace all M_1 and the volume integral all M_2 . [Gauss.]

10. Considering single cylinder of radius a for which the force depends only on $f(r)$ i.e. we have a cylindrical distribution.

$F = 0$ at $r = 0$ (no force at center)

$F = -2\pi p r^2$ for $r < a$ (inside)

$F = -2\pi p a^2$ for $r > a$ (outside)

For a point inside the cylinder $r < a$, the force is $F = -2\pi p r^2$. The potential V is given by $V = -\int F dr = -\int -2\pi p r^2 dr = \frac{2\pi p r^3}{3} + C_1$.

For a point outside the cylinder $r > a$, the force is $F = -2\pi p a^2$. The potential V is given by $V = -\int F dr = -\int -2\pi p a^2 dr = 2\pi p a^2 r + C_2$.

From considering that when $r = a$ there are no discontinuities in the potential, we have $V_1 = V_2$ at $r = a$. This gives $\frac{2\pi p a^3}{3} + C_1 = 2\pi p a^2 a + C_2$, which simplifies to $C_1 = 2\pi p a^2 (2 \log a - 1) + C_2$.

Hence $V = -2\pi p a^2 \log r + 2\pi p a^2 (2 \log a - 1) + C_1$ for $r > a$.

Here $C_1 = \infty$, but this does not prevent us from getting equipotential surfaces. We are interested chiefly with ∇V i.e. the D of a const. = 0.

For a point in empty space $V = V_1 + V_2$ (two cylinders).

$$V = -2\pi f [a^2 \log r_1 + b^2 \log r_2 + C_1 + C_2 + D_1 + D_2]$$

$$= C \text{ (const.)}$$

Then we have over the other side r

$$a^2 \log r_1 + b^2 \log r_2 = C$$

or for our present case $r_1, r_2 = \text{const.}$

12. A sphere of radius 3 inches and of constant density μ is surrounded by a spherical shell concentric with it of radii 4 inches and 5 inches and of density μr , where r is the distance from the centre. Compute the values of the attraction and of the potential function at all points in space and draw curves to illustrate the fact that V and $D_r V$ are everywhere continuous and that $D_r^2 V$ is discontinuous at certain points.

13. A very long cylinder of radius 4 inches and of constant density μ is surrounded by a cylindrical shell coaxial with it and of radii 6 inches and 8 inches. The density of this shell is inversely proportional to the square of the distance from the axis, and at a point 8 inches from this axis is μ . Use the Theorem of Gauss to find the values of V , $D_r V$, and $D_r^2 V$ at different points on a line perpendicular to the axis of the cylinder at its middle point. If the value of the attraction at a distance of 20 inches from the axis is 10, show how to find μ .

14. Use Dirichlet's value of $D_x V$, given by equation [78], to find the attraction in the direction of the axis of x at points within a spherical shell of radii r_0 and r_1 and of constant density ρ .

15. Are there any other cases except those in which the density of the attracting matter depends only upon the distance from a plane, from an axis, or from a central point, where surfaces of equal force are also equipotential surfaces? Prove your assertion.

16. Prove that if a mass M_1 be divided up into elements, and if each one of these elements be multiplied by the value at one of its own points of the potential function V_2 due to another mass M_2 , the limit of the sum of these infinitesimal products will be equal to the limit of the sum extended over M_2 of the product of the masses of its elements by the corresponding values of the potential function due to M_1 . That is, show that

$$\int V_2 \cdot dM_1 = \int V_1 \cdot dM_2,$$

where the sinister integral is to embrace all M_1 and the dexter all M_2 . [Gauss.]

17. Two uniform straight wires of length l and of masses m_1 and m_2 are parallel to each other and perpendicular to the line joining their middle points, which is of length y_1 . Show that the amount of work required to increase the distance between the wires to y_2 by moving one of them parallel to itself is

$$\frac{2 m_1 m_2}{l^2} \left[y - \sqrt{l^2 + y^2} - l \log \frac{\sqrt{l^2 + y^2} - l}{y} \right]_{y=y_1}^{y=y_2} \quad [\text{Minchin.}]$$

18. Show that if the earth be supposed spherical and covered with an ocean of small depth, and if the attraction of the particles of water on each other be neglected, the ellipticity of the ocean spheroid will be given by the equation,

$$e^2 = \frac{\text{The centrifugal force at the equator}}{g}$$

19. A spherical shell whose inner radius is r contains a mass m of gas which obeys the Law of Boyle and Mariotte. Find the law of density of the gas, the total normal pressure on the inside of the containing vessel, and the pressure at the centre.

20. If the earth were melted into a sphere of homogeneous liquid, what would be the pressure at the centre in tons per square foot? If this molten sphere instead of being homogeneous had a surface density of 2.4 and an average density of 5.6, what would be the pressure at the centre on the supposition that the density increased proportionately to the depth?

21. A solid sphere of attracting matter of mass m and of radius r is surrounded by a given mass M of gas which obeys the Law of Boyle and Mariotte. If the whole is removed from the attraction of all other matter, find the law of density of the gas and the pressure on the outside of the sphere.

22. The potential function within a closed surface S due to matter wholly outside the surface has for extreme values the extreme values upon S .

23. If the potential functions V and V' due to two systems of matter without a closed surface have the same values at all points on the surface, they will be equal throughout the space enclosed by the surface.

24. The potential function outside of a closed surface due to matter wholly within the surface has for its extreme values two of the following three quantities : zero and the extreme values upon the surface.

25. Prove that if R is the distance from the origin of coördinates to the point P , and if V_P is the value at P of the potential function of any system of attracting masses within a finite distance of the origin, the limit as R is made infinite of $V_P \cdot P$ is equal to M , the whole quantity of attracting matter.

CHAPTER III.

THE POTENTIAL FUNCTION IN THE CASE OF
REPULSION.

39. Repulsion, according to the Law of Nature. Certain physical phenomena teach us that bodies may acquire, by electrification or otherwise, the property of repelling each other, and that the resulting force of repulsion between two bodies is often much greater than the force of attraction which, according to the Law of Gravitation, every body has for every other body.

Experiment shows that almost every such case of repulsion, however it may be explained physically, can be quantitatively accounted for by assuming the existence of some distribution of a kind of "matter," every particle of which is supposed to repel every other particle of the same sort according to the "Law of Nature," that is, roughly stated, with a force directly proportional to the product of the quantities of matter in the particles, and inversely proportional to the square of the distance between their centres.

In this chapter we shall assume, for the sake of argument, that such matter exists, and proceed to discuss the effects of different distributions of it. Since the law of repulsion which we have assumed is, with the exception of the opposite directions of the forces, mathematically identical with the law which governs the attraction of gravitation between particles of ponderable matter, we shall find that, by the occasional introduction of a change of sign, all the formulas which we have proved to be true for cases of attraction due to gravitation can be made useful in treating corresponding problems in repulsion.

40. Force at Any Point due to a Given Distribution of Repelling Matter. Two equal quantities of repelling matter concentrated at points at the unit distance apart are called "unit quantities" when they are such as to make the force of repulsion between them the unit force.

If the ratio of the quantity of repelling matter within a small closed surface supposed drawn about a point P , to the volume of the space enclosed by the surface, approaches the limit ρ when the surface (always enclosing P) is supposed to be made smaller and smaller, ρ is called the "density" of the repelling matter at P .

In order to find the magnitude at any point P of the force due to any given distribution of repelling matter, we may suppose the space occupied by this matter to be divided up into small elements, and compute an approximate value of this force on the assumption that each element repels a unit quantity of matter concentrated at P with a force equal to the quantity of matter in the element divided by the square of the distance between P and one of the points of the element. The limit approached by this approximate value as the size of the elements is diminished indefinitely is the value required.

FIG. 30.

Let Q (Fig. 30), whose coördinates are x' , y' , z' , be the corner next the origin of an element of the distribution. Let ρ be the density at Q and $\Delta x' \Delta y' \Delta z'$ the volume of the element; then the force at P due to the matter in the element is approxi-

mately equivalent to a force of magnitude $\frac{\rho \Delta x' \Delta y' \Delta z'}{PQ^2}$ acting in the direction QP , or a force of magnitude $-\frac{\rho \Delta x' \Delta y' \Delta z'}{PQ^2}$ acting in the direction PQ . If the coördinates of P are x, y, z , the component of this force in the direction of the positive axis of x is $\frac{-\rho \Delta x' \Delta y' \Delta z' (x' - x)}{[(x' - x)^2 + (y' - y)^2 + (z' - z)^2]^{\frac{3}{2}}}$, and the force at P parallel to the axis of x due to the whole distribution of repelling matter is

$$X = - \iiint \frac{\rho (x' - x) dx' dy' dz'}{[(x' - x)^2 + (y' - y)^2 + (z' - z)^2]^{\frac{3}{2}}}, \quad [125_a]$$

where the triple integration is to be extended over the whole space filled with the repelling matter. For the components of the force at P parallel to the other axes we have, similarly,

$$Y = - \iiint \frac{\rho (y' - y) dx' dy' dz'}{[(x' - x)^2 + (y' - y)^2 + (z' - z)^2]^{\frac{3}{2}}}, \quad [125_b]$$

and

$$Z = - \iiint \frac{\rho (z' - z) dx' dy' dz'}{[(x' - x)^2 + (y' - y)^2 + (z' - z)^2]^{\frac{3}{2}}}. \quad [125_c]$$

If we denote by V the function

$$\iiint \frac{\rho dx' dy' dz'}{[(x' - x)^2 + (y' - y)^2 + (z' - z)^2]^{\frac{3}{2}}}, \quad [126]$$

which, together with its first derivatives, is everywhere finite and continuous, as we have shown in the last chapter, it is easy to see that

$$X = -D_x V, \quad Y = -D_y V, \quad Z = -D_z V, \quad [127]$$

$$R = \sqrt{(D_x V)^2 + (D_y V)^2 + (D_z V)^2}, \quad [128]$$

and that the direction-cosines of the line of action of the resultant force at P are

$$-\frac{D_x V}{R}, \quad -\frac{D_y V}{R}, \quad \text{and} \quad -\frac{D_z V}{R}. \quad [129]$$

It follows from this (see Section 21) that the component in any direction of the force at a point P due to any distribution M of repelling matter is minus the value at P of the partial derivative of the function V taken in that direction.

The function V goes by the name of the Newtonian potential function whether we are dealing with attracting or repelling matter.

In the case of repelling matter, it is evident that the resultant force on a particle of the matter at any point tends to drive that particle in a direction which leads to points at which the potential function has a lower value, whereas in the case of gravitation a particle of ponderable matter at any point tends to move in a direction along which the potential function increases.

41. The Potential Function as a Measure of Work. It is easy to show by a method like that of Article 27 that the amount of work required to move a unit quantity of repelling matter, concentrated at a point, from P_1 to P_2 , in face of the force due to any distribution M of the same kind of matter, is $V_2 - V_1$, where V_1 and V_2 are the values at P_1 and P_2 respectively of the potential function due to M . The farther P_1 is from the given distribution, the smaller is V_1 , and the less does $V_2 - V_1$ differ from V_2 . In fact, the value of the potential function at the point P_2 , wherever it may be, measures the work which would be required to move the unit quantity of matter by any path from "infinity" to P_2 .

42. Gauss's Theorem in the Case of Repelling Matter. If a quantity m of repelling matter is concentrated at a point within a closed oval surface, the resultant force due to m at any point on the surface acts toward the outside of the surface instead of towards the inside, as in the case of attracting matter.

Keeping this in mind, we may repeat the reasoning of Article 31, using repelling matter instead of attracting matter, and substituting all through the work the exterior normal for the interior normal, and in this way prove that :

If there be any distribution of repelling matter partly within and partly without a closed surface T , and if M be the whole quantity of this matter enclosed by T , and M' the quantity outside T , the surface integral over T of the component in the direction of the *exterior* normal of the force due to both M and M' is equal to $4\pi M$. If V be the potential function due to M and M' , we have

$$\int D_n V \cdot ds = 4\pi M.$$

43. Poisson's Equation in the Case of Repelling Matter. If we apply the theorem of the last article to the surface of a volume element cut out of space containing repelling matter, and use the notation of Article 35, we shall find that in the case of rectangular coördinates the surface integral, taken over the element, of the component in the direction of the exterior normal is

$$\Delta x \Delta y \Delta z \left[\frac{\Delta_x X}{\Delta x} + \frac{\Delta_y Y}{\Delta y} + \frac{\Delta_z Z}{\Delta z} \right] = 4\pi \rho_0 \cdot \Delta x \Delta y \Delta z, \quad [130]$$

where X is the average component in the positive direction of the axis of x of the force on the elementary surface $\Delta y \Delta z$, and where Y and Z have similar meanings. It is evident that if the element be made smaller and smaller, X , Y , and Z will approach as limits the components parallel to the coördinate axes of the force at P . These components are $-D_x V$, $-D_y V$, and $-D_z V$; so that if we divide [130] by $\Delta x \Delta y \Delta z$ and then decrease indefinitely the dimensions of the element, we shall arrive at the equation

$$\nabla^2 V = -4\pi\rho. \quad [131]$$

By using successively cylinder coördinates and spherical coördinates we may prove the equations

$$\frac{1}{r} D_r (r D_r V) + \frac{1}{r^2} D_\theta^2 V + D_z^2 V = -4\pi\rho, \quad [132]$$

and

$$\sin \theta \cdot D_r (r^2 D_r V) + \frac{D_\phi^2 V}{\sin \theta} + D_\theta (\sin \theta \cdot D_\theta V) = -4\pi\rho r^2 \sin \theta, \quad [133]$$

so that Poisson's Equation holds whether we are dealing with attracting or repelling matter.

44. Coexistence of Two Kinds of Active Matter. Certain physical phenomena may be most conveniently treated mathematically by assuming the coexistence of two kinds of "matter" such that any quantity of either kind repels all other matter of the same kind according to the Law of Nature, and attracts all matter of the other kind according to the same law.

Two quantities of such matter may be considered equal if, when placed in the same position in a field of force, they are subjected to resultant forces which are equal in intensity and which have the same line of action. The two quantities of matter are of the same kind if the direction of the resultant forces is the same in the two cases, but of different kinds if the directions are opposed. The unit quantity of matter is that quantity which concentrated at a point would repel with the unit force an equal quantity of the same kind concentrated at a point at the unit distance from the first point.

It is evident from Articles 2, 14, and 40 that m units of one of these kinds of matter, if concentrated at a point (x, y, z) and exposed to the action of $m_1, m_2, m_3, \dots, m_k$ units of the same kind of matter concentrated respectively at the points $(x_1, y_1, z_1), (x_2, y_2, z_2), (x_3, y_3, z_3), \dots, (x_k, y_k, z_k)$, and of $m_{k+1}, m_{k+2}, \dots, m_n$ units of the other kind of matter concentrated respectively at the points $(x_{k+1}, y_{k+1}, z_{k+1}), (x_{k+2}, y_{k+2}, z_{k+2}), \dots, (x_n, y_n, z_n)$, will be urged in the direction parallel to the positive axis of x with the force

$$X = -m \sum_{i=1}^{i=k} \frac{m_i (x_i - x)}{r_i^3} + m \sum_{i=k+1}^{i=n} \frac{m_i (x_i - x)}{r_i^3}, \quad [134]$$

where r_i is the distance between the points (x, y, z) and (x_i, y_i, z_i) .

If we agree to distinguish the two kinds of matter from each other by calling one kind "positive" and the other kind "negative," it is easy to see that if every m which belongs to positive

matter be given the plus sign and every m which belongs to negative matter the minus sign, we may write the last equation in the form

$$X = -m \sum_{i=1}^{i=n} \frac{m_i (x_i - x)}{r_i^3}. \quad [135]$$

The result obtained by making m in [135] equal to unity is called the force at the point (x, y, z) .

In general, m units of either kind of matter concentrated at the point (x, y, z) , and exposed to the action of any continuous distribution of matter, will be urged in the positive direction of the axis of x by the force

$$X = -m \iiint \frac{\rho (x' - x) dx' dy' dz'}{[(x' - x)^2 + (y' - y)^2 + (z' - z)^2]^{\frac{3}{2}}}; \quad [136]$$

in this expression, ρ , the density at (x', y', z') , is to be taken positive or negative according as the matter at the point is positive or negative: m is to have the sign belonging to the matter at the point (x, y, z) : and the limits of integration are to be chosen so as to include all the matter which acts on m .

With the same understanding about the signs of m and of ρ , it is clear that the force which urges in any direction s , m units of matter concentrated at the point (x, y, z) is equal to $-m \cdot D_s V$, where V is the everywhere finite, continuous, and single-valued function

$$\iiint \frac{\rho (x' - x) dx' dy' dz'}{[(x' - x)^2 + (y' - y)^2 + (z' - z)^2]^{\frac{3}{2}}};$$

and that $m V$ measures the amount of work required to bring up from "infinity" by any path to its present position the m units of matter now at the point (x, y, z) .

If we call the resultant force which would act on a unit of positive matter concentrated at the point P "the force at P ," it is clear that if any closed surface T be drawn in a field of force due to any distribution of positive and negative matter so as to include a quantity of this matter algebraically equal to Q ,

the surface integral taken over T of the component in the direction of the exterior normal of the force at the different points of the surface is equal to $4\pi Q$.

It will be found, indeed, that all the equations and theorems given earlier in this chapter for the case of one kind of repelling matter may be used unchanged for the case where positive and negative matter coexist, if we only give to ρ and m their proper signs.

It is to be noticed that Poisson's Equation is applicable whether we are dealing with attracting matter or repelling matter, or positive and negative matter existing together.

EXAMPLES.

1. Show that the extreme values of the potential function outside a closed surface S , due to a quantity of matter algebraically equal to zero within the surface, are its extreme values on S .

2. Show that if the potential function due to a quantity of matter algebraically equal to zero and shut in by a closed surface S has a constant value all over the surface, then this constant value must be zero.

CHAPTER IV.

SURFACE DISTRIBUTIONS.—GREEN'S THEOREM.

45. Force due to a Closed Shell of Repelling Matter. If a quantity of very finely-divided repelling matter be enclosed in a box of any shape made of indifferent material, it is evident from [127] and from the principles of Section 38 that if the volume of the box is greater than the space occupied by the repelling matter, the latter will arrange itself so that its free surface will be equipotential with regard to all the active matter in existence, taking into account any there may be outside the box as well as that inside. It is easy to see, moreover, that we shall have a shell of matter lining the box and enclosing an empty space in the middle.

That any such distribution as that indicated in the subjoined diagram is impossible follows immediately from the reasoning of Section 37. For ABC and DEF are parts of the same

FIG. 31.

equipotential free surface of the matter. If we complete this surface by the parts indicated by the dotted lines, we shall enclose a space void of matter and having therefore throughout a value of the potential function equal to that on the bounding

surface. But in this case all points which can be reached from O by paths which do not cut the repelling matter must be at the same potential as O , and this evidently includes all space not actually occupied by the repelling matter; which is absurd.

Let us consider, then (see Fig. 32), a closed shell of repelling matter whose inner surface is equipotential, so that at every point of the cavity which the shell shuts in, the resultant force, due to the matter of which the shell is composed and to any outside matter there may be, is zero.

Let us take a small portion ω of the bounding surface of the cavity as the base of a tube of force which shall intercept an

FIG. 32.

area ω' on an equipotential surface which cuts it just outside the outer ω surface of the shell, and let us apply Gauss's Theorem to the box enclosed by ω , ω' , and the tube of force. If F' is the average value of the resultant force on ω' , the only part of the surface of the box which yields anything to the surface integral of normal force, we have

$$F' \omega' = 4 \pi m,$$

where m is the quantity of matter within the box. If we multiply and divide by ω , this equation may be written

$$F' = \frac{4 \pi m}{\omega} \cdot \frac{\omega}{\omega'}. \quad [137]$$

If ω be made smaller and smaller, so as always to include a given point A , ω' as it approaches zero will always include a point B on the line of force drawn through A , and F' will approach the value F of the resultant force at B .

The shell may be regarded as a thick layer spread upon the

$F = \int \frac{\Delta V}{\Delta n} = 0.$
 $\Delta V = 0$
 all over

inner surface, and in this case the limit of $\frac{m}{\omega}$ may be considered the value at A of the rate at which the matter is spread upon the surface. If we denote this limit by σ , we shall have

$$F = 4\pi\sigma \cdot \lim_{\omega \doteq 0} \left(\frac{\omega}{\omega'} \right). \quad [138]$$

If B be taken just outside the shell, and if the latter be very thin, $\lim_{\omega \doteq 0} \left(\frac{\omega}{\omega'} \right)$ evidently differs little from unity; and we see that the resultant force at a point just outside the outer surface of a shell of matter, whose inner surface is equipotential, becomes more and more nearly equal to 4π times the quantity of matter per unit of surface in the distribution at that point as the shell becomes thinner and thinner.

The reader may find out for himself, if he pleases, whether or not the line of action of the resultant force at a point just outside such a shell as we have been considering is normal to the shell.

It is to be carefully noticed that the inner surface of a closed shell need not be equipotential unless the matter composing the shell is finely divided and free to arrange itself at will.

When the shell is thin, and we regard it as formed of matter spread upon its inner surface, σ is called the "surface density" of the distribution, and its value at any point of the inner surface of the shell may be regarded as a measure of the amount of matter which must be spread upon a unit of surface if it is to be uniformly covered with a layer of thickness equal to that of the shell at the point in question.

46. Surface Distributions. It often becomes necessary in the mathematical treatment of physical problems, on the assumption of the existence of a kind of repelling matter or agent, to imagine a finite quantity of this agent *condensed on a surface* in a layer so thin that for practical purposes we may leave the thickness out of account. If a shell like that considered in the last section could be made thinner and thinner by compression

while the quantity of matter in it remained unchanged, the volume density (ρ) of the shell would grow larger and larger without limit, and σ would remain finite. A distribution like this, which is considered to have *no* thickness, is called a surface distribution.

The value at a point P of the potential function due to a superficial distribution of surface density σ is the surface integral, taken over the distribution, of $\frac{\sigma}{r}$, where r is the distance from P .

It is evident that as long as P does not lie exactly in the distribution, the potential function and its derivatives are always finite and continuous, and the force at any point in any direction may be found by differentiating the potential function partially with regard to that direction.

If ρ were infinite, the reasoning of Article 22 would no longer apply to points actually in the active matter, and it is worth our while to prove that in the case of a surface distribution where σ is everywhere finite, the value at a point P of the potential function due to the distribution remains finite, as

FIG. 33.

P is made to move normally through the surface at a point of finite curvature.

To show this, take the point O (Fig. 33), where P is to cut the surface, as origin, and the normal to the surface at O as

the axis of x , so that the other coördinate axes shall lie in the tangent plane.

If the curvature in the neighborhood of O is finite, it will be possible to draw on the surface about O a closed line such that for every point of the surface within this line the normal will make an acute angle with the axis of x .

For convenience we will draw the closed line of such a shape that its projection on the tangent plane shall be a circle whose centre is at O and whose radius is U , and we will cut the area shut in by this line into elements of such shape that their projections upon the tangent plane shall divide the circle just mentioned into elements bounded by concentric circumferences drawn at radial intervals of Δu , and by radii drawn at angular distances of $\Delta\phi$.

If $x, 0, 0$ are the coördinates of the point P , x', y', z' those of a point of one of the elements of the area shut in by the closed line, and α the angle which the normal to the surface at this point makes with the axis of x , the size of the surface element is approximately $\frac{u \Delta u \Delta\phi}{\cos\alpha}$, where $u^2 = z'^2 + y'^2$, and the value at P of the potential function due to that part of the surface distribution shut in by the closed line is

$$V_1 = \int_0^{2\pi} d\phi \int_0^U \frac{\sigma u du}{\cos\alpha \sqrt{(x-x')^2 + u^2}}. \quad [139]$$

The quantity

$$\frac{\sigma u}{\cos\alpha \sqrt{(x-x')^2 + u^2}} = \frac{\sigma \sec\alpha}{\sqrt{1 + \left(\frac{x-x'}{u}\right)^2}}$$

is always finite, for, whatever the value of the quantity under the radical sign in the last expression may be when x, x' , and u are all zero, it cannot be less than unity, and therefore V_1 must be finite even when P moves down the axis of x to the surface itself.

If V and V_2 are the values at P of the potential functions due respectively to all the existing acting matter and to that

part of this matter not lying on the portion of the surface shut in by our closed line, we have $V = V_1 + V_2$, and, since P is a point outside the matter which gives rise to V_2 , the latter is finite; so that V is finite.

The reader who wishes to study the properties of the derivatives of the potential function, and their relations to the force components at points actually in a surface distribution, will find the whole subject treated in the first part of Riemann's *Schwere, Electricität und Magnetismus*.

Using the notation of this section, it is easy to write down definite integrals which represent the values of the potential function at two points on the same normal, one on one side of a superficial distribution, and at a distance a from it, and the other on the other side at a like distance, and to show that the difference between these integrals may be made as small as we like by choosing a small enough. This shows that the value of the potential function at a point P changes continuously, as P moves normally through a surface distribution of finite superficial density. If matter could be concentrated upon a geometric line, so that there should be a finite quantity of matter on the unit of length of the line, or if a finite quantity of matter could be really concentrated at a point, the resulting potential function would be infinite on the line itself, and at the point.

47. The Normal Force at Any Point of a Surface Distribution. In the case of a strictly superficial distribution on a closed surface where the repelling matter is free to arrange itself at will, the inner surface of the matter (and hence the outer surface, which is coincident with it) is equipotential, and the resultant force at a point B just outside the distribution is normal to the surface and numerically equal to 4π times the surface density at B . This shows that the derivative of the potential function in the direction of the normal to the surface has values on opposite sides of the surface differing by $4\pi\sigma$, and at the surface itself cannot be said to have any definite value.

It is easy, however, to find the force with which the repelling matter composing a superficial distribution is urged outwards. For, take a small element ω of the surface as the base of a tube of force, and apply Gauss's Theorem to a box shut in by the surface of distribution, the tube of force, and a portion ω' of an equipotential surface drawn just outside the distribution. Let F and F' be the average forces at the points of ω and ω' respectively, then the surface integral of normal forces taken over the box is $F'\omega' - F\omega$, and this, since the only active matter is concentrated on the surface of the box (see Section 31), is equal to $2\pi\sigma_0\omega$, where σ_0 is the average surface density at the points of the element ω . This gives us

$$F = F' \frac{\omega'}{\omega} - 2\pi\sigma_0.$$

Now let the equipotential surface of which ω' is a part be drawn nearer and nearer the distribution; then

$$\lim \frac{\omega'}{\omega} = 1, \quad \lim F' = 4\pi\sigma_0, \quad \text{and} \quad F = 2\pi\sigma_0.$$

F is the average force which would tend to move a unit quantity of repelling matter concentrated successively at the different points of ω in the direction of the exterior normal, but the actual distribution on ω is $\omega\sigma_0$, so that this matter presses on the medium which prevents it from escaping with the force $2\pi\sigma_0^2\omega$; and, in general, the pressure exerted on the resisting medium which surrounds a surface distribution of repelling matter is at any point $2\pi\sigma^2$ per unit of surface, where σ is the surface density of the distribution at the point in question.

We may imagine a superficial distribution of matter which is fixed, instead of being free to arrange itself at will. In this case the surface of the matter will not be in general equipotential, but, if we apply Gauss's Theorem to a box shut in by a slender tube of force traversing the distribution, and by two surfaces drawn parallel to the distribution and close to it, one on one side and one on the other, we may prove that the

normal component of the force at a point just outside the distribution differs by $4\pi\sigma$ from the normal component, in the same sense, of the force at a point just inside the distribution on the line of force which passes through the first point.

48. Green's Theorem. Before proving a very general theorem due to Green,* of which what we have called Gauss's Theorem is a special case, we will show that if T is any closed surface and U a function of x , y , and z , which for every point inside T is finite, continuous, and single-valued,

$$\iiint D_x U \cdot dx dy dz = \int U \cdot D_n x \cdot ds, \quad [140]$$

where the first integral is to include all the space shut in by T , and the second is to be taken over the whole surface, and where $D_n x$ represents the partial derivative of x taken in the direction of the *exterior* normal.

To prove this, choose the coördinate axes so that T shall lie in the first octant, and divide the space inside the contour of the

FIG. 34.

projection of T on the plane yz into elements of size $dy dz$. On each of these elements erect a right prism cutting T twice or some other even number of times. Let us call the values of U at the successive points where the edge nearest the axis of x of

* George Green, *An Essay on the Application of Mathematical Analysis to the Theories of Electricity and Magnetism*. Nottingham, 1828.

any one of these prisms cuts T , U_1 , U_2 , U_3 , ... U_{2n} respectively; the angles which this edge makes with exterior normals drawn to T at these points, α_1 , α_2 , α_3 , ... α_{2n} ; and the elements which the prism cuts from the surface T , ds_1 , ds_2 , ds_3 , ... ds_{2n} . It is evident that wherever a line perpendicular to the plane yz cuts *into* T , the corresponding value of α is obtuse and its cosine negative, but wherever such a line cuts *out* of T , the corresponding value of α is acute and its cosine positive.

Keeping this in mind, we shall see that although the base of a prism is the common projection of all the elements which it cuts from T , and in absolute value is approximately equal to any one of these multiplied by the corresponding value of $\cos \alpha$, yet, since $dx dy$, ds_1 , ds_2 , etc., are all positive areas and some of the cosines are negative, we must write, if we take account of signs,

$$dy dz = -ds_1 \cos \alpha_1 = +ds_2 \cos \alpha_2 = -ds_3 \cos \alpha_3 = \dots$$

If the indicated integration with regard to x in the left-hand member of [140] be performed and the proper limits introduced, we shall have

$$\iiint D_x U dx dy dz = \iint dy dz [-U_1 + U_2 - U_3 + U_4 - \dots], \quad [141]$$

where the double sign of integration directs us to form a quantity corresponding to that in brackets for every prism which cuts T , to multiply this by the area of the base of the prism, and to find the limit of the sum of all the results as the bases of the prisms are made smaller and smaller.

Since we may substitute for $dy dz$ any one of its approximate values given above, we may write the quantity within the brackets

$$U_1 \cos \alpha_1 ds_1 + U_2 \cos \alpha_2 ds_2 + U_3 \cos \alpha_3 ds_3 + \dots,$$

and this shows that the double integral is equivalent to the surface integral, taken over the whole of T , of $U \cos \alpha$, whence we may write

$$\iiint D_x U \cdot dx dy dz = \int U \cos \alpha ds, \quad [142]$$

where the first integral is to be taken all through the space shut in by T , and the second over the whole surface.

Let $P(x, y, z)$ be any point of T , α , β , and γ the angles which the exterior normal drawn to P at T makes with the coördinate axes, and P' a point on this normal at a distance Δn from P . The coördinates of P' are

$$x + \Delta n \cdot \cos \alpha, \quad y + \Delta n \cdot \cos \beta, \quad z + \Delta n \cdot \cos \gamma,$$

and if $W = f(x, y, z)$ be any continuous function of the space coördinates,

$$W_P = f(x, y, z),$$

$$\begin{aligned} W_{P'} &= f(x + \Delta n \cos \alpha, y + \Delta n \cos \beta, z + \Delta n \cos \gamma) \\ &= f(x, y, z) + \Delta n \cos \alpha \cdot D_x f + \Delta n \cos \beta \cdot D_y f \\ &\quad + \Delta n \cos \gamma D_z f + (\Delta n)^2 Q, \end{aligned}$$

and

$$\frac{W_{P'} - W_P}{PP'} = \cos \alpha \cdot D_x f + \cos \beta \cdot D_y f + \cos \gamma \cdot D_z f + \Delta n \cdot Q,$$

whence

$$\lim \frac{W_{P'} - W_P}{PP'} = D_n W_P = \cos \alpha D_x f + \cos \beta D_y f + \cos \gamma D_z f. \quad [143]$$

If, as a special case, $W = x$, we have $D_n x = \cos \alpha$; so that [142] may be written

$$\iiint D_x U \cdot dx dy dz = \int U D_n x \cdot ds, \quad [144]$$

which we were to prove.*

Green's Theorem, which follows very easily from this result, may be stated in the following form :

If U and V are any two functions of the space coördinates which together with their first derivatives with respect to these coördinates are finite, continuous, and single-valued throughout the space shut in by any closed surface T , then, if n refers to an exterior normal,

* This theorem has been virtually proved already in Sections 29 and 36.

$$\begin{aligned} & \iiint (D_x U \cdot D_x V + D_y U \cdot D_y V + D_z U \cdot D_z V) dx dy dz \\ &= \int U \cdot D_n V \cdot ds - \iiint U \cdot \nabla^2 V \cdot dx dy dz \quad [145] \end{aligned}$$

$$= \int V \cdot D_n U \cdot ds - \iiint V \cdot \nabla^2 U \cdot dx dy dz, \quad [146]$$

where the triple integrals include all the space within T and the single integrals include the whole surface.

$$\text{Since} \quad D_x U \cdot D_x V = D_x (U \cdot D_x V) - U \cdot D_x^2 V,$$

we have

$$\begin{aligned} & \iiint D_x U \cdot D_x V \cdot dx dy dz \\ &= \iiint D_x (U \cdot D_x V) dx dy dz - \iiint U \cdot D_x^2 V \cdot dx dy dz; \end{aligned}$$

but, from [144],

$$\iiint D_x (U \cdot D_x V) dx dy dz = \int U \cdot D_x V \cdot D_n x \cdot ds,$$

whence

$$\begin{aligned} & \iiint (D_x U \cdot D_x V) dx dy dz \\ &= \int U \cdot D_x V \cdot D_n x \cdot ds - \iiint U \cdot D_x^2 V \cdot dx dy dz. \quad [147] \end{aligned}$$

If we form the two corresponding equations for the derivatives with regard to y and z , and add the three together, we shall obtain an expression which, by the use of [143], reduces immediately to [145]. Considerations of symmetry give [146].

If we subtract [146] from [145], we get

$$\begin{aligned} & \iiint (U \cdot \nabla^2 V - V \cdot \nabla^2 U) dx dy dz \\ &= \int (U \cdot D_n V - V \cdot D_n U) ds. \quad [148] \end{aligned}$$

In applying Green's Theorem to such spaces as those marked T_0 in the adjoining diagrams, it is to be noticed that the walls of the cavities, marked S' and S'' , as well as the surfaces,

Green's Theorem for two dimensions.

$$\iiint (D_x U \cdot D_x V + D_y U \cdot D_y V + D_z U \cdot D_z V) dx dy dz$$

$$= \int U D_n V \cdot dS - \iiint U \cdot \nabla^2 V dx dy dz$$

marked S, for parts of the boundaries of the spaces, a difference. the surface integrals, which the theorem declares must be taken. Take any curve in the xy plane, & consider a rt. cyl. on it as base & the height being = c, and apply Green's Th. to space inside.

$$\iiint (D_x U \cdot D_x V + D_y U \cdot D_y V + D_z U \cdot D_z V) dx dy dz$$

$$= c \iint (D_x U \cdot D_x V + D_y U \cdot D_y V) dx dy$$

In $\int U \cdot D_n V \cdot dS$ boundaries of the spaces are to be extended over S' and S'' as well as over S . We must remember, however, they have same value on neither end of cyl. surface but one is positive other is -ve.

\therefore over two ends $\int U \cdot D_n V \cdot dS = 0$

Also $\iiint U \cdot \nabla^2 V \cdot dx dy dz = c \iint U \cdot \nabla^2 V \cdot dx dy$

Hence, equating,

$$\iint (D_x U \cdot D_x V + D_y U \cdot D_y V) dx dy$$

and (over surface) $\int U \cdot D_n V \cdot dS = \iint U \cdot \nabla^2 V \cdot dx dy$

(around contour) (over surface)

The triple integral on the left hand side of the equation is the whole amount of matter (algebraically considered, where we have both positive and negative matter) within T, and the dexter is

Unique solution. Take a prob. in heat conduction wherein $\nabla^2 u = 0$ - Let us be a solid which satisfies diff. eqn & boundary conditions. This is the only solution -

For I. If in [145] we make $\nabla^2 w = 0$ & put w as before the potential function due to any distribution of actual matter within or without T, we shall have

Now $\iint w = 0$ on surface $\iint R^2 dx dy dz = \iint V \cdot D_n w \cdot dS + \iiint \rho \cdot w dx dy dz$ [145]

Apply G.T. to space enclosed by solid - where R is the resultant force at the point (x, y, z).

$$\iiint [(D_x w)^2 + (D_y w)^2 + (D_z w)^2] dx dy dz$$

$$= \int w D_n w \cdot dS - \iiint (w \nabla^2 w) dx dy dz$$

" " " "

$$\iiint [(D_x w)^2 + (D_y w)^2 + (D_z w)^2] dx dy dz = 0$$

(over)

90

$$\int \nabla^2 U \cdot \nabla U \cdot d\mathbf{a} =$$

... difference ...

$$\iiint (D_x U \cdot D_x V + D_y U \cdot D_y V + D_z U \cdot D_z V) dx dy dz$$

... in the ... plane ...

$$\int \nabla U \cdot \nabla V \cdot d\mathbf{a} = \int \nabla^2 V \cdot U \cdot d\mathbf{a} \quad [145]$$

$$\int \nabla^2 U \cdot U \cdot d\mathbf{a} = \int \nabla U \cdot \nabla U \cdot d\mathbf{a} \quad [146]$$

where the triple integrals include all the space within T and the single integrals include the whole surface.

... each $D_x w = 0$ as each is positive ...

we have $\iiint \nabla^2 (U \cdot \nabla U) dx dy dz = \int \nabla U \cdot \nabla U \cdot d\mathbf{a}$

but from [141] ...

$$\iiint \nabla^2 (U \cdot \nabla U) dx dy dz = \int \nabla U \cdot \nabla U \cdot d\mathbf{a}$$

whence

$$\iiint (D_x U \cdot D_x V + D_y U \cdot D_y V + D_z U \cdot D_z V) dx dy dz = \int \nabla U \cdot \nabla V \cdot d\mathbf{a} \quad [147]$$

If we form the two corresponding equations for the derivatives with regard to y and z , and add the three together, we shall obtain an expression which, by the use of [143], reduces immediately to [145]. Considerations of symmetry give [146].

If we subtract [146] from [145], we get

$$0 = \int \nabla U \cdot \nabla U \cdot d\mathbf{a} - \int \nabla U \cdot \nabla U \cdot d\mathbf{a} = 0$$

In applying Green's Theorem to such spaces as those marked T in the adjoining diagrams, it is noticed that the walls of the cavities, marked S' and S'' , as well as the surfaces

$$\int \nabla^2 w \cdot w \cdot d\mathbf{a} = \int \nabla w \cdot \nabla w \cdot d\mathbf{a}$$

$$0 = \int \nabla^2 w \cdot w \cdot d\mathbf{a} = \int \nabla w \cdot \nabla w \cdot d\mathbf{a}$$

marked S , form parts of the boundaries of the spaces, and that the surface integrals, which the theorem declares must be taken

FIG. 35.

over the whole boundaries of the spaces, are to be extended over S' and S'' as well as over S . We must remember, however, that an exterior normal to T_0 at S' points *into* the cavity C' .

49. Special Cases under Green's Theorem. I. If in [148] V be the potential function due to any distribution either of repelling matter or of positive and negative matter existing together, whether this matter is within or without T , and if $U = 1$, we have

$$\nabla^2 V = -4\pi\rho, \quad \text{--- Observed to be true? Hence}$$

and
$$4\pi \iiint \rho \, dx \, dy \, dz = \int [-D_n V] \, ds. \quad [149]$$

The triple integral on the left-hand side of the equation is the whole amount of matter (algebraically considered, where we have both positive and negative matter) within T , and the dexter is the surface integral taken over T of the force in the direction of the exterior normal; so that [149] expresses Gauss's Theorem.

II. If in [145] we make U equal to V , and let this represent as before the potential function due to any distribution of actual matter within or without T , we shall have

$$\iiint R^2 \, dx \, dy \, dz = \int V \cdot D_n V \, ds + 4\pi \iiint \rho V \, dx \, dy \, dz, \quad [150]$$

where R is the resultant force at the point (x, y, z) .

III. If in [145] we make $U = V = u$, any function which within the closed surface T satisfies the equation $\nabla^2 u = 0$, we shall have

$$\iiint [(D_x u)^2 + (D_y u)^2 + (D_z u)^2] dx dy dz = \int u \cdot D_n u \cdot ds. \quad [151]$$

IV. If in [148] V is the potential function due to two distributions of active matter, M_1 inside the closed surface T and M_2 outside it, and if $U = \frac{1}{r}$ where r is the distance of the point (x, y, z) from a fixed point O , we must consider separately the two cases where O is respectively without T and within T .

A. If O is without T , $\nabla^2 \left(\frac{1}{r}\right) = 0$ for points within the surface. Also, $\nabla^2 V = -4\pi\rho$, so that

$$\int \frac{D_n V}{r} ds - \int V \cdot D_n \left(\frac{1}{r}\right) ds = -4\pi \iiint \frac{\rho}{r} dx dy dz.$$

FIG. 36.

The triple integral is evidently equal to the value at the point O of the potential function due to M_1 alone. If we call this V_1 , and notice (see [143]) that $D_n r$ at any point of T is the cosine of the angle δ between r and the exterior normal to T , we have

$$\int \frac{D_n V}{r} ds - \int \frac{V \cos \delta}{r^2} ds = -4\pi V_1. \quad [152]$$

If T is a surface equipotential with respect to the joint action of M_1 and M_2 , and if we denote by V_s the constant value of V on T , we have

$$\int \frac{D_n V}{r} ds - V_s \int \frac{\cos \delta}{r^2} ds = -4\pi V_1,$$

and it is easy to show, by the reasoning used in Section 31, that $\int \frac{\cos \delta}{r^2} ds = 0$, whence

$$V_1 = -\frac{1}{4\pi} \int \frac{D_n V}{r} ds. \quad [153]$$

B. If O is a point inside T , whether or not it is within M_1 , and if T is equipotential with respect to the action of M_1 and M_2 , we will surround O by a small spherical surface s' of radius r' , and apply [148] to the space lying inside T and without the spherical surface. In doing so, it is to be noticed that s' forms part of the boundary of the region we are dealing with, and that an exterior normal to the region at s' will be an interior normal of the sphere.

FIG. 37.

Since for all points of the region we are considering $\nabla^2 \left(\frac{1}{r} \right) = 0$, we have

$$\begin{aligned} \int \frac{D_n V}{r} ds - \int \frac{D_{r'} V}{r'} ds' - V_s \int D_n \left(\frac{1}{r} \right) ds + \int V D_{r'} \left(\frac{1}{r'} \right) ds' \\ = -4\pi \iiint \frac{\rho}{r} dx dy dz; \end{aligned} \quad [154]$$

or, since $ds' = r'^2 d\omega'$, where $d\omega'$ is the area which the elementary cone whose base is ds' and vertex O intercepts on the sphere of unit radius drawn about O ,

$$\begin{aligned} \int \frac{D_n V}{r} ds + V_s \int \frac{\cos \delta}{r^2} ds - r' \int D_{r'} V \cdot d\omega' - \int V d\omega' \\ = -4\pi \iiint \frac{\rho}{r} dx dy dz. \end{aligned} \quad [155]$$

It is easily proved, by the reasoning of Section 31, that

$$\int \frac{\cos \delta}{r^2} ds = 4\pi,$$

and it is clear that if r' be made smaller and smaller, the third integral of [155] approaches the limit zero. If V' is the average value of V on the surface s' ,

$$\int V' d\omega' = V' \int d\omega = V' 4\pi;$$

and as r' is made smaller and smaller, this approaches the value $4\pi V_o$, where V_o is the value of V at O . The value, when r' is zero, of the triple integral in [155] is evidently V_1 , and we have

$$\int \frac{D_n V}{r} ds + 4\pi V_s - 4\pi V_o = -4\pi V_1. \quad [156]$$

If V_2 is the value at O of the potential function due to M_2 alone, $V_o = V_1 + V_2$, so that [156] may be written in the form

$$V_s - V_2 = -\frac{1}{4\pi} \int \frac{D_n V}{r} ds. \quad [157]$$

If T is not equipotential with respect to the action of M_1 and M_2 , we have

$$4\pi V_2 = \int \frac{D_n V}{r} ds - \int V D_n \left(\frac{1}{r} \right) ds. \quad [158]$$

V. If in [148] we make $U = \frac{1}{r}$, where r is the distance of the point (x, y, z) from a fixed point O , and if $V = v$, a function which within the closed surface T satisfies the equation $\nabla^2 v = 0$, we shall have

$$4\pi v = \int v D_n \left(\frac{1}{r} \right) ds - \int \frac{D_n v}{r} ds, \quad [159]$$

if O is within T , and

$$\int \frac{D_n v}{r} ds = \int v \cdot D_n \left(\frac{1}{r} \right) ds, \quad [160]$$

if O is outside T .

50. The Surface Distributions Equivalent to Certain Volume Distributions. Keeping the notation of IV. in the last article, let T be a closed surface equipotential with respect either to the joint action of two distributions of matter, M_1 inside T and M_2 outside it, or (when M_2 equals zero) to the action of a single distribution within the surface; and let V_1 , V_2 , and V be the values of the potential functions due respectively to M_1 alone, to M_2 alone, and to M_1 and M_2 existing together. If a quantity of matter were condensed on T so as to give at every point a surface density equal to $\frac{-D_n V}{4\pi}$, the whole quantity of matter on the surface would be

$$\frac{-1}{4\pi} \int D_n V \cdot ds,$$

and this, by [149], is equal in amount to M_1 . Let us study the effect of removing M_1 from the inside of T and spreading it in a superficial distribution M_1' over T , so that the surface density at every point shall be $\frac{-D_n V}{4\pi}$. In what follows, it is assumed

that we have two distributions of matter, one inside the closed surface and the other outside. It is to be carefully noted, however, that by putting M_2 equal to zero in our equations, all our results are applicable to the case where we have an equipotential surface surrounding all the matter, which may be all of one kind or not.

The value, at any point O , of the potential function due to the joint effect of M_2 and the surface distribution M_1' , would be

$$V_o = V_2 - \frac{1}{4\pi} \int \frac{D_n V}{r} \cdot ds.$$

If O is an outside point, we have, by [153],

$$V_o = V_2 + V_1,$$

so that the effect at any point outside an equipotential surface of a quantity M_1 of matter anyhow distributed inside the surface is the same as that of an equal quantity of matter distributed over the surface in such a way that the superficial

density at every point is $\frac{-D_n V}{4\pi}$, where V is the value of the potential function due to the joint action of M_1 and any matter (M_2) that may be outside the surface.

If O is an inside point, we have, by [157],

$$V_o = V_2 + V_s - V_2 = V_s, \quad [161]$$

which shows that the joint effect of M_2 and M_1' is to give to all points within and upon the surface the same constant value of the potential function which points upon the surface had before M_1 was displaced by M_1' . If, therefore, M_1' and M_2 exist without M_1 , there is no force at any point of the cavity shut in by T ; or, in other words, the force due to M_1' alone is at all points inside T equal and opposite to that due to M_2 .

If M_1 and M_2 exist without M_1' , the cavity enclosed by T is, in general, a field of force. M_1' acts as a screen to shield the space within T from the action of M_2 .

The surface of M_1' is equipotential with respect to all the active matter, so that there is no tendency of the matter composing the surface distribution to arrange itself in any different manner upon T .

51. The potential function V , due to any distribution of matter whose volume density ρ is everywhere finite, satisfies the following conditions:

(1) V and its first space derivatives are everywhere finite and continuous, and are equal to zero at an infinite distance from the attracting mass.

(2) If R is the distance from the origin of coördinates to the point P ,

$$\lim_{R=\infty} (V_P \cdot R) = M,$$

where M is a definite constant.

(3) Except at the surface of the attracting mass, or at some other surface where ρ is discontinuous,

$$\nabla^2 V = -4\pi\rho,$$

where ρ is to be put equal to zero outside of the attracting mass.

It is easy to show from Green's Theorem that for a given value of ρ as a function of x , y , and z , only one function which will satisfy these three conditions exists.

Suppose, for the sake of argument, that there are two such functions, V and V' , and put $u = V - V'$. It is evident that u satisfies conditions (1) and (2), and that $\nabla^2(u) = 0$ except where ρ is discontinuous. Parallel to each surface of discontinuity, and very near to it, draw two surfaces, one on each side, so as to shut in the places where $\nabla^2 u$ is not zero, and draw a spherical surface about the origin, using a radius R large enough to enclose all the surfaces of discontinuity.

If now we apply [151] to that part of the space inside the spherical surface and not shut in by the barriers which we have drawn, and if we notice that each pair of parallel barriers together yields nothing to the surface integral, we shall have

$$\iiint [(D_x u)^2 + (D_y u)^2 + (D_z u)^2] dx dy dz = \int u \cdot D_n u \cdot ds,$$

where the dexter integral is to be extended over the spherical surface only.

If $d\omega$ is the solid angle of the infinitesimal cone which intercepts the element ds from the spherical surface, we have

$$\int u D_n u ds = R^2 \int u D_R u d\omega.$$

Now since u satisfies condition (2) above, it is easy to show that if we make R grow larger and larger, this surface integral approaches the value zero as a limit, for u approaches the value $\frac{M}{R}$ and $D_R u$ the value $\frac{-M}{R^2}$, so that the whole integral approaches the value $\frac{-4\pi M}{R}$, which, when R is made infinite, approaches the value zero.

If we embrace all space in our sphere, we shall have

$$\iiint (D_x u)^2 + (D_y u)^2 + (D_z u)^2 dx dy dz = 0,$$

whence $D_x u = 0$, $D_y u = 0$, $D_z u = 0$.

Therefore u is constant in all space, and since it is zero at infinity, must be everywhere zero, so that $V = V'$.

52. Thomson's Theorem or Dirichlet's Principle. We will now prove a theorem* which is usually called Dirichlet's Principle by Continental writers, but which in English books is generally attributed to Sir W. Thomson. This theorem, in its simplest form, asserts that there always exists one, but no other than this one, function, v , of x, y, z , which (1) is finite, continuous, and single-valued, together with its first space derivatives, throughout a given closed region L ; (2) at every point of the region satisfies the equation $\nabla^2 v = 0$; and (3) at every point on the boundary of the region has any arbitrarily assigned value, provided that this can be regarded as the value at that point of a single-valued function which has derivatives finite, continuous, and single-valued all over this boundary.

There is evidently an infinite number of functions which satisfy the first and third conditions. If, for instance, the equation of the bounding surface S of the region is $F(x, y, z) = 0$, and if the value of v at the point (x, y, z) upon this surface is to be $f(x, y, z)$, any function of the form

$$\Phi(x, y, z) \cdot F(x, y, z) + f(x, y, z)$$

would satisfy the third condition, whatever finite function Φ might be.

If we assign to the function to be found a constant value C all over S , $v \equiv C$ will satisfy all three of the conditions given above.

One can prove that if there is one solⁿ there is no other. But it is hard to prove that there is one ~~posⁿ~~ solution.

If the sought function is to have different values at different points of S , and if for u in the integral

$$Q = \iiint [(D_x u)^2 + (D_y u)^2 + (D_z u)^2] dx dy dz,$$

which is to be extended over the whole of the region, we substitute any one of all the functions which satisfy conditions (1) and (3), the resulting value of Q will be positive. Some one at least of these functions (v) must, however, yield a value of Q which though positive, is so small that no other one can make Q smaller. Let h be an arbitrary constant to which some value has been assigned, and let w be any function which satisfies condition (1) and is equal to zero at all parts of S , then $U = v + hw$ will satisfy conditions (1) and (3), and conversely, there is no function which satisfies these two conditions which cannot be written in the form $U = v + hw$, where h is an arbitrary constant, and w a function which is zero at S and which satisfies condition (1).

Not done
Proved
Schwartz

Call the minimum value of Q due to v , Q_v , and the value of Q due to U , Q_U , then

$$Q_U = Q_v + 2h \iiint (D_x v \cdot D_x w + D_y v \cdot D_y w + D_z v \cdot D_z w) dx dy dz + h^2 \iiint [(D_x w)^2 + (D_y w)^2 + (D_z w)^2] dx dy dz,$$

which, since w is zero at the boundary of the region, may be written, by the help of Green's Theorem,

$$Q_U - Q_v = -2h \iiint w \nabla^2(v) dx dy dz + h^2 \Omega^2.$$

Now since Q_v is the minimum value of Q , no one of the infinite number of values of $Q_U - Q_v$ formed by changing h and w under the conditions just named can be negative; but if $\nabla^2 u$ were not everywhere equal to zero within L , it would be easy to choose w so that the coefficient of $2h$ in the expression for $Q_U - Q_v$ should not be zero, and then to choose h so that $Q_U - Q_v$ should be negative. Hence $\nabla^2 v$ is equal to zero through-

out L , and there always exists at least one function which satisfies the three conditions stated above.

There is only one such function; for if beside v there were another $u = v + hw$, we should have, since the coefficient of h is zero when $\nabla^2(u) = 0$,

$$Q_u = Q_v + h^2\Omega^2,$$

and, that Q_u may be as small as Q_v , $h\Omega$ must be zero, whence either $h = 0$ or $\Omega = 0$, and if $\Omega = 0$, w is zero. Therefore, $u = v$, and there is only one function which in any given case satisfies all the three conditions given above.

By applying the same reasoning to the space outside a closed surface S and inside a spherical surface of large radius R which is finally made infinite, it is easy to prove that there always exists in the space outside a closed surface S one and only one function v which (1) has a given value at every point of S , (2) satisfies the equation $\nabla^2 v = 0$, (3) together with its first derivatives, is finite and continuous outside S , and (4) is such that the limit, as R becomes infinite, of Rv is a definite, finite constant.

These theorems help us to prove other theorems, of which two are of considerable interest for us.

I. If a function $v = f(x, y, z)$, together with its first space derivatives, is finite and continuous in all space outside a surface S , and outside this surface satisfies the equation $\nabla^2 v = 0$, and if $v\sqrt{x^2 + y^2 + z^2}$ approaches a definite, finite, constant limit as the point (x, y, z) moves away from the origin to infinity, then this function may be considered to be the potential function of a surface distribution of matter upon S .

In order to prove this, we will first apply [160] to v' , the function which has on S the same value as v , which inside S is, with its first derivatives, finite and continuous, and which satisfies the equation $\nabla^2 v' = 0$; and use the space inside S as our region. This gives

$$\int v D_n \left(\frac{1}{r} \right) ds = \int \frac{D_n v'}{r} ds,$$

where n refers to the exterior normal of S .

If we now apply [159] to the function v , using as a field the space outside S and within a spherical surface S' of large radius R , drawn about the point O as centre, we shall have

$$4\pi v_o = - \int v D_n \left(\frac{1}{r} \right) ds - \int \frac{D_n v}{r} ds + \frac{1}{R^2} \int v ds' + \frac{1}{R} \int D_R v \cdot ds',$$

where n is made to refer to the same normal as before by a change of sign in the first two integrals. If now we combine the two equations just obtained, and make R infinite, so that the last two integrals of the second equation shall vanish, we shall have

$$v_o = + \frac{1}{4\pi} \int (D_n v' - D_n v) \frac{ds}{r},$$

which is the value at an outside point of the potential function due to a superficial distribution of surface density $\frac{1}{4\pi} (D_n v' - D_n v)$ spread upon S .

It is to be noticed that the letter r refers to a point without S in each of the last three equations. Instead of one closed surface we might have several, as it is easy to prove by introducing as many Dirichlet's functions as there are surfaces.

We will state the second theorem, leaving the proof, which is almost identical in form with the one just given, for the reader.

II. If a function $v' = F(x, y, z)$ satisfies the equation $\nabla^2 v' = 0$ throughout the space enclosed by a closed surface S , and within this space, together with its first derivatives, is everywhere finite and continuous, it may be considered to be the potential function within this space of a surface distribution on S .

The superficial density of this distribution will be found to be

$$\frac{1}{4\pi} (D_n v' - D_n v),$$

where v is the function which has the same value on S that v' has, and outside S satisfies the equation $\nabla^2(v) = 0$ and the other conditions given above.

It follows, from these theorems, that we may assign any continuously arranged arbitrary values to the potential function at

the different points of a closed surface S , make these values the common values on the surface of the functions v and v' , and assert that a distribution of matter on S of surface density $\sigma = \frac{1}{4\pi}(D_n v' - D_n v)$ would give rise to a potential function having the chosen values on S . In this case v and v' would be the values in regions respectively without and within S of the potential function due to this surface distribution. It is, then, always possible to distribute matter in one and only one way upon a given closed surface so that the value of the potential function due to the matter shall have given values all over the surface.

EXAMPLES.

1. Prove that there always exists one, but no other than this one, function, v , which, together with its first space derivatives, is finite, continuous, and single-valued everywhere within a given region L , has values at the boundary of the region equal to those of an arbitrarily chosen, finite, continuous, and single-valued function, $f(x, y, z)$, and satisfies at every point in L the equation

$$D_x(K \cdot D_x v) + D_y(K \cdot D_y v) + D_z(K \cdot D_z v) = 0,$$

where K is a function positive within L .

2. If the potential function due to a certain distribution of matter is given equal to zero for all space external to a given closed surface S and equal to $\phi(x, y, z)$, where ϕ is a continuous single-valued function zero at all points of S , for all space within S ; there is no matter without S , there is a superficial distribution of surface density

$$\sigma = \frac{1}{4\pi} [(D_x \phi)^2 + (D_y \phi)^2 + (D_z \phi)^2]^{\frac{1}{2}}$$

upon S , and the volume density of the matter within S is

$$\rho = -\frac{1}{4\pi} [D_x^2 \phi + D_y^2 \phi + D_z^2 \phi].$$

[Thomson and Tait.]

CHAPTER V.

ELECTROSTATICS AND ELECTROKINEMATICS.

53. Introductory. Having considered abstractly a few of the characteristic properties of what has been called “the Newtonian potential function,” we will devote this chapter to a very brief discussion of some general principles of Electrostatics and Electrokinematics. By so doing we shall incidentally learn how to apply to the treatment of certain practical problems many of the theorems that we have proved in the preceding chapters.

In what follows, the reader is supposed to be familiar with such electrostatic phenomena as are described in the first few chapters of treatises on Statical Electricity, and with the hypotheses that are given to explain these phenomena.

Without expressing any opinion with regard to the physical nature of what is called *electrification*, we shall here take for granted that whether it is due to the presence of some substance, or is only the consequence of a mode of motion or of a state of polarization, we may, without error in our results, use some of the language of the old “Two Fluid Theory of Electricity” as the basis of our mathematical work.

The reader is reminded that, among other things, this theory teaches that:—

(1) Every particle of a body which is in its natural state contains, combined together so as to cancel each other’s effects at all outside points, equal large quantities of two kinds of *electricity* with properties like those of the positive and negative “matter” described in Section 44.

(2) Electrification consists in destroying in some way the equality between the amounts of the two kinds of electricity which a body, or some part of a body, naturally contains, so that there shall be an excess or *charge* of one kind. If the

charge is of positive electricity, the body is said to be positively electrified; if the charge is negative, negatively electrified. Either kind of electricity existing uncombined with an equal quantity of the other kind, is called *free* electricity.

(3) When a charged body A is brought into the neighborhood of another body B in its natural state, the two kinds of electricity in every particle of B tend to separate from each other, one being attracted and the other repelled by A 's charge, and to move in opposite directions.

In general, a tendency to separation occurs in all parts of the body, whether it is charged or not, where the resultant electric force (the force due to all the free electricity in existence) is not zero. This effect is said to be due to *induction*.

In our work we shall assume all this to be true, and proceed to apply the principles stated in Section 44 to the treatment of problems involving distributions of electricity. We shall find it convenient to distinguish between *conductors*, which offer practically no resistance to the passage of electricity through their substance, and *nonconductors*, which we shall regard as preventing altogether such transfer of electricity from part to part.

54. The Charges on Conductors are Superficial. When electricity is communicated to a conductor, a state of equilibrium is soon established. After this has taken place, there can be no resultant force tending to move any portion of the charge through the substance of the conductor, for, by supposition, the conductor does not prevent the passage of electricity through itself.

Moreover, the resultant electric force must be zero at all points in the substance of a conductor in electric equilibrium; for if the force were not zero at any point, electricity would be produced by induction at that point, and carried away through the body of the conductor under the action of the inducing force.

From this it follows that the potential function V , due to all the free electricity in existence, must be constant throughout

the substance of any single conductor in electric equilibrium, whether or not the conductor be charged, and whether or not there be other charged or uncharged conductors in the neighborhood. Different conductors existing together will in general be at different potentials, but all the points of any one of these conductors will be at the same potential.

Wherever V is constant, $\nabla^2 V = 0$, and hence, by Poisson's Equation, $\rho = 0$, so that there can be no free electricity within the substance of a conductor in equilibrium, and the whole charge must be distributed upon the surface. Experiment shows that we must regard the thickness of charges spread upon conductors as inappreciable, and that it is best to consider that in such cases we have to do with really superficial distributions of electricity, in which the conductor bears a rough analogy to the cavity enclosed by the thin shells of repelling matter described in the preceding chapter.

The surface density at any point of a superficial distribution of electricity shall be taken positive or negative, according as the electricity at that point is positive or negative, and the force which would act upon a unit of positive electricity if it were concentrated at a point P without disturbing existing distributions shall be called "the electric force" or "the strength of the electric field at P ."

It is evident, from Sections 45 and 46, that the electric force at a point just outside a charged conductor, at a place where the surface density of the charge is σ , is $4\pi\sigma$, and that this is directed outwards or inwards, according as σ is positive or negative.

In other words, $D_n V$, the derivative of the potential function in the direction of the exterior normal, is equal to $-4\pi\sigma$, and the value of V at a point P just outside the conductor is greater or less than its value within the conductor, according as the surface density of the conductor's charge in the neighborhood of P is negative or positive.

It is to be carefully noted that, although the surface of a conductor must always be equipotential, the superficial density of

the conductor's charge need not be the same at all parts of the surface. We shall soon meet with cases where the electricity on a conductor's surface is at some points positive and at others negative, and with other cases where the sign of the potential function inside and on a conductor is of opposite sign to the charge.

It is evident, from the work of Section 47, that the resistance per unit of area which the nonconducting medium about a conductor has to exert upon the conductor's charge to prevent it from flying off, is, at a part where the density is σ , $2\pi\sigma^2$.

55. General Principles which follow directly from the Theory of the Newtonian Potential Function. If two different distributions of electricity, which have the same system of equipotential surfaces throughout a certain region, be superposed so as to exist together, the new distribution will have the same equipotential surfaces in that region as each of the components. For, if V_1 and V_2 , the potential functions due to the two components respectively, be both constant over any surface, their sum will be constant over the same surface.

Two distributions of electricity, which have densities everywhere equal in magnitude but opposite in sign, have the same system of equipotential surfaces, and, if superposed, have no effect at any point in space.

Two distributions of electricity, arranged successively on the same conductor so that at every point the density of the one is m times that of the other, have the same system of equipotential surfaces, and the potential function due to the first is everywhere m times as great as that due to the second.

If the whole charge of a conductor which is not exposed to the action of any electricity except its own is zero, the superficial density must be zero at all points of the surface, and the conductor is in its natural state. For if σ is not everywhere zero, it must be in some places positive and in others negative; and, according to the work of the last section, the potential function V , due to this charge, must have, somewhere outside

the conductor, values higher and lower than V_0 , its value in the conductor itself. But this would necessitate somewhere in empty space a value of the potential function not lying between V_0 and 0, the value at infinity; that is, a maximum in empty space if V_0 is positive, and a minimum if V_0 is negative; which is absurd.

A system of conductors, on each of which the charge is null, must be in the natural state if exposed to the action of no outside electricity. For, by applying the reasoning just used to that conductor in which the potential function is supposed to have the value most widely different from zero, we may show that the surface density all over the conductor is zero, so that no influence is exercised on outside bodies; and then, supposing this conductor removed, we may proceed in the same way with the system made up of the remaining conductors.

If a charge M of electricity, when given to a conductor, arranges itself in equilibrium so as to give the surface density $\sigma = f(x, y, z)$ and to make the potential function $V_0 = \int \frac{\sigma ds}{r}$ constant within the conductor, a charge $-M$, if arranged on the conductor so as to give at every point the density $-\sigma = -f(x, y, z)$ would be in equilibrium, for it would give everywhere the potential function $\int \frac{-\sigma \cdot ds}{r} = -V_0$, and this is constant wherever V_0 is constant.

Only one distribution of the same quantity of electricity M on the same conductor, removed from the influence of all other electricity, is possible; for, suppose two different values of surface density possible, $\sigma_1 = f_1(x, y, z)$ and $\sigma_2 = f_2(x, y, z)$, then $-\sigma_2 = -f_2(x, y, z)$ is a possible distribution of the charge $-M$. Superpose the distribution $-\sigma_2$ upon the distribution σ_1 so that the total charge shall be equal to zero; then the surface density at every point is $\sigma_1 - \sigma_2$, and this must be zero by what we have just proved, so that $\sigma_1 = \sigma_2$.

Since we may superpose on the same conductor a number of distributions, each one of which is by itself in equilibrium, it is

easy to see that if the whole quantity of electricity on any conductor be changed in a given ratio, the density at each point will be changed in the same ratio.

56. Tubes of Force and their Properties. We have seen that a unit of positive electricity concentrated at a point P just outside a conductor would be urged away from the conductor or drawn towards it, according as that point on the conductor which is nearest P is positively or negatively electrified. If we regard lines of force drawn in an electric field as generated by points moving *from* places of higher potential *to* places of lower potential, we may say that a line of force *proceeds from* every point of a conductor where the surface density is positive, and that a line of force *ends at* every point of a conductor where the surface density is negative. No line of force either leaves or enters a conductor at a point where the surface density is zero, and no line of force can start at one point of a conductor where the electrification is positive and return to the same conductor at a point where the electrification is negative. No line of force can proceed from one conductor at a point electrified in any way and enter another conductor at a point where the electrification has the same name as at the starting-point. A line of force never cuts through a conductor so as to come out at the other side, for the force at every point inside a conductor is zero.

Lines and tubes of force are sometimes called in electrostatics lines and tubes of "induction."

When a tube of force joins two conductors, the charges Q_1 , Q_2 of the portions S_1 , S_2 which it cuts from the two surfaces are

FIG. 38.

made up of equal quantities of opposite kinds of electricity. For if we suppose the tube of force to be arbitrarily prolonged

and closed at the ends inside the two conductors, the surface integral of normal force taken over the box thus formed is zero, for the part outside the conductors yields nothing, since the resultant force is tangential to it, and there is no resultant force at any point inside a conductor. It follows, from Gauss's Theorem, that the whole quantity of electricity ($Q_1 + Q_2$) inside the box must be zero, or $Q_1 = -Q_2$, which proves the theorem. If σ_1 and σ_2 are the average values of the surface densities of the charges on S_1 and S_2 respectively, we have $\sigma_1 S_1 = Q_1$ and $\sigma_2 S_2 = Q_2$, whence

$$\sigma_2 = -\sigma_1 \frac{S_1}{S_2} \quad [162]$$

The integral taken over any surface, closed or not, of the force normal to that surface is called by some writers the *flow of force* across the surface in question, and by others the *induction* through this surface.

If we apply Gauss's Theorem to a box shut in by a tube of force and the portions S_1, S_2 which it cuts from any two equipotential surfaces, we shall have, if the box contains no electricity,

$$F_2 S_2 - F_1 S_1 = 0, \quad [163]$$

where F_1 and F_2 are the average values, over S_1 and S_2 respectively, of the normal force taken in the same direction (that in which V decreases) in both cases. In other words, the flow of force across all equipotential sections of a tube of force containing no electricity is the same, or the average force over an equipotential section of an empty tube of force is inversely proportional to the area of the section.

FIG. 39.

$$\begin{aligned} F_1 S_1 &= F_2 S_2 \\ F_3 S_3 &= F_2 S_2 + 4\pi m \\ F_4 S_4 &= F_3 S_3 \end{aligned}$$

When a tube of force encounters a quantity m of electricity (Fig. 39), the flow of force through the tube on passing this

electricity is increased by $4\pi m$. If, however, the tube encounters a conductor large enough to close its end completely, a charge m will be found on the conductor just sufficient to reduce to zero the flow of force (I) through the tube. That is,

$$m = -\frac{I}{4\pi}.$$

It is sometimes convenient to consider an electric field to be divided up by a system of tubes of force, so chosen that the flow of force across any equipotential surface of each tube shall be equal to 4π . Such tubes are called *unit tubes*; for wherever one of them abuts on a conductor, there is always the unit quantity of electricity on that portion of the conductor's surface which the tube intercepts. In some treatises on electricity the term "line of force" is used to represent a unit tube of force, as when a conductor is said to cut a certain number of "lines of force."

It is evident that m unit tubes abut on a surface just outside a conductor charged with m units of either kind of electricity, if the superficial density of the charge has everywhere the same sign. These tubes must be regarded as *beginning* at the conductor if m is positive, and as *ending* there if m is negative. If a conductor is charged at some places with positive electricity and at others with negative electricity, tubes of force will begin where the electrification is positive, and *others* will end where the electrification is negative.

It is evident that no tube of force can return into itself.

FIG. 40.

57. Hollow Conductors. When the nonconducting cavity, shut in by a hollow conductor K (Fig. 40), contains quantities

of electricity (m_1, m_2, m_3 , etc., or $\sum m$) distributed in any way, but insulated from K , there is induced on the walls of the cavity a charge of electricity algebraically equal in quantity, but opposite in sign, to the algebraic sum of the electricity within the cavity.

Call the outside surface of the conductor S_o and its charge M_o , the boundary of the cavity S_i and its charge M_i , and surround the cavity by a closed surface S , every point of which lies within the substance of the conductor, where the resultant force is zero. Now the surface integral of normal force taken over S is zero, so that, according to Gauss's Theorem, the algebraic sum of the quantities of electricity within the cavity and upon S_i is zero. That is,

$$M_i + m_1 + m_2 + m_3 + \dots = M_i + \sum (m) = 0, \quad [164]$$

and this is our theorem, which is true whatever the charge on S_o is, and whatever distribution of free electricity there may be outside K . If the distribution of the electricity within the cavity be changed by moving m_1, m_2 , etc., to different positions, the *distribution* of M_i on S_i will in general be changed, although its value remains unchanged.

If K has received no electricity from without, its total charge must be zero; that is,

$$M_o = -M_i = \sum (m).$$

If a charge algebraically equal to M be given to K ,

$$M_o = M - M_i.$$

The combined effect of $\sum (m)$, the electricity within the cavity, and M_i , the electricity on the walls of the cavity, is at all points without S_i absolutely null. For, if we apply [153] to S , any surface drawn in the conductor so as to enclose S_i , we shall have $D_n V$ everywhere zero, since the potential function is constant within the conductor; this shows that V_1 , the potential function due to

all the electricity within S , must be zero at all points without S ; but S may be drawn as nearly coincident with S_i as we please. Hence our theorem, which shows that, so far as the value of the potential function in the substance of the conductor or outside it, and so far as the arrangement of M_o and of M' , any free electricity there may be outside K , are concerned, M_i and $\sum (m)$ might be removed together without changing anything. The potential function at all points outside S_i is to be found by considering only M and M' .

If S_i happens to be one of the equipotential surfaces of $\sum (m)$ considered by itself, M_i will be arranged in the same way as a charge of the same magnitude would arrange itself on a conductor whose outside surface was of the shape S_i , if removed from the action of all other free electricity.

The potential function (V_2) due to M_o and M' is constant everywhere within S_o ; for if we apply [157] to a surface S , drawn within the substance of the conductor as near S_o as we like, we shall have

$$V_s - V_o = 0,$$

which proves the theorem.

The potential function within the cavity is equal to $V_2 + V_1$, where V_1 is the potential function due to M_i and $\sum (m)$. Of these, V_2 is, as we have seen, constant throughout K and the cavity (Section 31) which it encloses, while V_1 has different values in different parts of the cavity, and is zero within the substance of the conductor.

Suppose now that, by means of an electrical machine, some of the two kinds of electricity existing combined together in a conductor within the cavity be separated, and equal quantities (q) of each kind be set free and distributed in any manner within the cavity.

The value of V_1 within the cavity will probably be different from what it was before, but V_2 will be unchanged; for the

quantity of matter in the cavity is unchanged, being now, algebraically considered,

$$\sum (m) + q - q = \sum (m),$$

so that M_i is unchanged, although it may have been differently arranged on S_i , in order to keep the value of V_1 zero within the substance of the conductor. If now a part of the free electricity in the cavity be conveyed to S_i in some way, the substance of the conductor will still remain at the same potential as before. For, if l units of positive electricity and n units of negative electricity be thus transferred to S_i , the whole quantity of free electricity within the cavity will be $\sum (m) - l + n$, and that on S_i will be $M_i + l - n$: but these are numerically equal, but opposite in sign, and the charge on S_i , if properly arranged, suffices, without drawing on M_o to reduce to zero the value of V_1 in K . Since M_o and M' remain as before, V_2 is unchanged, and the conductor is at the same potential as before. So long as no electricity is introduced into the cavity from *without* K , no electrical charges within the cavity can have any effect outside S_i .

Most experiments in electricity are carried on in rooms, which we can regard as hollows in a large conductor, the earth. V_2 , the value of the potential function in the earth and the walls of the room, is not changed by anything that goes on inside the room, where the potential function is $V = V_1 + V_2$. Since we are generally concerned, not with the absolute value of the potential function, but only with its variations within the room, and since V_2 remains always constant, it is often convenient to disregard V_2 altogether, and to call V_1 the value of the potential function inside the room. When we do this we must remember that we are taking the value of the potential function in the earth as an arbitrary zero, and that the value of V_1 at a point in the room really measures only the difference between the values of the potential function in the earth and at the point in question. When a conductor A in the room is connected with the

walls of the room by a wire, the value of V_1 in A is, of course, zero, and A is said to have been *put to earth*.

58. Induced Charge on a Conductor which is put to Earth.

Suppose that there are in a room a number of conductors, viz. : A_1 charged with M_1 units of electricity, and A_2, A_3, A_4 , etc., connected with the walls of the room, and therefore at the potential of the earth, which we will take for our zero. If the potential function has the value p_1 inside A_1 , every point in the room outside the conductors must have a value of the potential function lying between p_1 and 0, else the potential function must have a maximum or a minimum in empty space. If p_1 is positive, there can be no positive electricity on the other conductors ; for if there were, lines of force must start from these conductors and go to places of lower potential ; but there are no such places, since these conductors are at potential zero, and all other points of the room at positive potentials. In a similar way we may prove that if p_1 is negative, the electricity induced on the other conductors is wholly positive.

Now let us apply [158] to a spherical surface, drawn so as to include A_1 and at least one of the other conductors, but with radius a so small that some parts of the surface shall lie within the room. If we take the point O at the centre of this surface, we shall have

$$4\pi V_2 = \frac{1}{a} \int D_r V \cdot ds + \frac{1}{a^2} \int V ds. \quad [165]$$

If M is the whole quantity of electricity within the spherical surface, there must be a quantity $-M$ outside the surface, either on the walls of the room or on conductors within the room. The value at O of the potential function, V_2 , due to the electricity without the sphere, is less in absolute value than $-\frac{M}{a}$, for it could only be as great as this if all the electricity outside the sphere were brought up to its surface.

By Gauss's Theorem,

$$\int D_r V \cdot ds = -4\pi M,$$

therefore,
$$\int V ds = 4 \pi a [M + a V_2]. \quad [166]$$

Now, if M_1 is positive, the integral is positive, for all parts of the spherical surface within the room yield positive differentials, and all other parts zero, so that the second side of the equation is positive. But $a V_2$ is of opposite sign to M , and is less in absolute value; hence, M is positive, and the total amount of negative electricity induced on the other conductors within the spherical surface by the charge on A_1 , is numerically less than this charge, unless some one of these conductors surrounds A_2 ; in which case the induced charge comes wholly on this conductor, while the other conductors, and the walls of the room, are free. Some of the tubes of force which begin at A_1 end on the walls of the room, provided these latter can be reached from A_1 without passing through the substance of any conductor.

59. Coefficients of Induction and Capacity. If a number of insulated conductors, A_2, A_3, A_4 , etc., are in a room in the presence of a conductor A_1 charged with M_1 units of electricity, the whole charge on each is zero; but equal amounts of positive and negative electricity are so arranged by induction on each, that the potential function is constant throughout the substance of every one of the conductors.

Let the values of the potential functions in the system of conductors be p_1, p_2, p_3, p_4 , etc. Since each conductor except A_1 is electrified, if at all, in some places with positive electricity, and in others with negative electricity, some lines of force must start from, and others end at, every such electrified conductor, so that there must be points in the air about each conductor at lower and at higher potentials than the conductor itself. But the value of the potential function in the walls of the room is zero, and there can be no points of maximum or minimum potential in empty space; so that p_1 must be that value of the potential function in the room most widely different from zero, and p_2, p_3, p_4 , etc., must have the same sign as p_1 .

The reader may show, if he likes, that both the negative part

and the positive part of the zero charge of any conductor, except A_1 , is less than M_1 .

Let p_{11} be the value of the potential function in a conductor A_1 charged with a single unit of electricity, and standing in the presence of a number of other conductors all uncharged and insulated. Then if p_{12}, p_{13}, p_{14} , etc., are, under these circumstances, the values of the potential functions in the other conductors, A_2, A_3, A_4 , etc., the potential functions in these conductors will be $M_1 p_{12}, M_1 p_{13}, M_1 p_{14}$, etc., if A_1 be charged with M_1 units of electricity instead of with one unit. This is evident, for we may superpose a number of distributions which are singly in equilibrium upon a set of conductors, and get a new distribution in equilibrium where the density is the sum of the densities of the component distributions, and the value of the resulting potential function the sum of the values of their potential functions.

If A_1 be discharged and insulated, and a charge M_2 be given to A_2 , the values of the potential functions in the different conductors may be written

$$M_2 p_{21}, M_2 p_{22}, M_2 p_{23}, M_2 p_{24}, \text{ etc.}$$

If now we give to A_1 and A_2 at the same time the charges M_1 and M_2 respectively, and keep the other conductors insulated, the result will be equivalent to superposing the second distribution, which we have just considered, upon the first, and the conductors will be respectively at potentials,

$$M_1 p_{11} + M_2 p_{21}, M_1 p_{12} + M_2 p_{22}, M_1 p_{13} + M_2 p_{23}, \text{ etc.} \quad [167]$$

If all the conductors are simultaneously charged with quantities M_1, M_2, M_3, M_4 , etc., of electricity respectively, the value of the potential function on A_k will be

$$V_k = M_1 p_{1k} + M_2 p_{2k} + M_3 p_{3k} + \dots + M_k p_{kk} + M_n p_{nk}, \quad [168]$$

Writing this in the form $V_k = a_k + M_k p_{kk}$, we see that if the charges on all the conductors except A_k be unchanged, a_k will be constant, and that every addition of $\frac{1}{p_{kk}}$ units of electricity to

the charge of A_k raises the value of the potential function in it by unity. If we solve the n equations like [168] for the charges, we shall get n equations of the form

$$M_k = V_1 q_{1k} + V_2 q_{2k} + V_3 q_{3k} + \cdots + V_k q_{kk} + \cdots + V_n q_{nk}, \quad [169]$$

where the q 's are functions of the p 's.

If all the conductors except A_k are connected with the earth, $M_k = V_k q_{kk}$, and q_{kk} is evidently the charge which, under these circumstances, must be given to A_k in order to raise the value of the potential function in it by unity. It is to be noticed that q_{kk} and $\frac{1}{P_{kk}}$ are in general different.

The charge which must be given to a conductor when all the conductors which surround it are in communication with the earth, in order to raise the value of the potential function within that conductor from zero to unity, shall be called the *capacity* of the conductor. It is evident that the capacity of a conductor thus defined depends upon its shape and upon the shape and position of the conductors in its neighborhood.

60. Distribution of Electricity on a Spherical Conductor.

Considerations of symmetry show that if a charge M be given to a conducting sphere of radius r , removed from the influence of all electricity except its own, the charge will arrange itself uniformly over the surface, so that the superficial density shall be everywhere $\sigma = \frac{M}{4\pi r^2}$.

The value, at the centre of the sphere, of the potential function due to the charge M on the surface is $\frac{M}{r}$, and, since the potential function is constant inside a charged conductor, this must be the value of the potential function throughout the sphere. If M is equal to r , $\frac{M}{r} = 1$; hence the capacity of a spherical conductor removed from the influence of all electricity except its own, is numerically equal to the radius of its surface.

61. Distribution of a Given Charge on an Ellipsoid. It is evident from the discussion of homœoids in Chapter I. that a charge of electricity arranged (on a conductor) in the form of a shell, bounded by ellipsoidal surfaces similar to each other (and to the surface of the conductor), and similarly placed, would be in equilibrium if the conductor were removed from the action of all electricity except its own. We may use this principle to help us to find the distribution of a given charge on a conducting ellipsoid.

Let us consider a shell of homogeneous matter bounded by two similar, similarly placed, and concentric ellipsoidal surfaces, whose semi-axes shall be respectively a, b, c , and $(1 + a)a, (1 + a)b, (1 + a)c$. If any line be drawn from the centre of the shell so as to cut both surfaces, the tangent planes to these two surfaces at the points of intersection will be parallel, and the distance between the planes is pa , where p is the length of the perpendicular let fall from the centre upon the nearer of the planes.

If ρ is the volume density of the matter of which the shell is composed, the mass of the shell is $M = \frac{4}{3} \pi abc [(1 + a)^3 - 1] \rho$, and the rate at which the matter is spread upon the unit of surface is, at any point, $\sigma = \rho \delta$, where δ is the thickness of the shell measured on the line of force which passes through the point in question. Eliminating ρ from these equations, we have

$$\sigma = \frac{M\delta}{4\pi abc [a + a^2 + \frac{1}{3}a^3]} \quad [170]$$

If, now, in accordance with the hypothesis that the thickness of the electric charge on a conductor is inappreciable, we make a smaller and smaller, noticing that δ differs from pa by an infinitesimal of an order higher than the first, we shall have for a strictly surface distribution,

$$\sigma = \frac{Mp}{4\pi abc} \quad [171]$$

If the equation of the surface of the ellipsoidal conductor is

$$\frac{x^2}{a^2} + \frac{y^2}{b^2} + \frac{z^2}{c^2} = 1,$$

we have

$$\frac{1}{p} = \sqrt{\frac{x^2}{a^4} + \frac{y^2}{b^4} + \frac{z^2}{c^4}},$$

and

$$\frac{c}{p} = \sqrt{c^2 \left(\frac{x^2}{a^4} + \frac{y^2}{b^4} \right) + 1 - \frac{x^2}{a^2} - \frac{y^2}{b^2}}.$$

This last expression shows that, as c is made smaller and smaller, σ approaches more and more nearly the value

$$\frac{M}{4\pi ab \sqrt{1 - \frac{x^2}{a^2} - \frac{y^2}{b^2}}}, \quad [172]$$

and this gives some idea of the distribution on a thin elliptical plate whose semi-axes are a and b .

For a circular plate, we may put $a = b$ in the last expression, which gives

$$\frac{M}{4\pi a \sqrt{a^2 - r^2}} \quad [173]$$

for the surface density at a point r units distant from the centre of the plate.

The charge M distributed according to this law on both sides of a circular plate of radius a raises the plate to potential

$$V = \frac{M}{a} \int_0^a \frac{dr}{\sqrt{a^2 - r^2}} = \frac{\pi M}{2a},$$

so that the capacity of the plate is

$$\frac{2a}{\pi}. \quad [174]$$

62. Spherical Condensers. If a conducting sphere A of radius r (Fig. 41) be surrounded by a concentric spherical conducting shell B of radii r_i and r_o and charged with m units of electricity while B is uncharged and insulated, we shall have

(1) the charge m uniformly distributed upon S , the surface of the sphere;

(2) an induced charge $-m$ (Section 57) uniformly distributed upon S_i , the inner surface of B ;

(3) a charge $+m$ (since the total charge of B is zero) uniformly distributed on S_o , the outer surface of B .

FIG. 41.

The value at the centre of the sphere of the potential function due to all these distributions is $V_A = \frac{m}{r} - \frac{m}{r_i} + \frac{m}{r_o}$, and this is the value of V throughout the conducting sphere. The value of the potential function in B is $V_B = \frac{m}{r_o}$.

If now a charge M be communicated to B , this will add itself to the charge m already existing on S_o , and the charge on S_i will be undisturbed. The values of the potential functions in the conductors are now

$$V_A = \frac{m}{r} - \frac{m}{r_i} + \frac{m+M}{r_o}, \quad \text{and} \quad V_B = \frac{m+M}{r_o}.$$

If now B be connected with the earth so as to make $V_B = 0$, the charges on S and S_i will be undisturbed, but the charge on S_o will disappear. V_A is now equal to $\frac{m}{r} - \frac{m}{r_i}$.

If A were uncharged, and B had the charge M , this charge would be uniformly distributed upon S_o , for, since the whole charge on S is zero, the whole charge on S_i must be zero also. It is easy to see that S and S_i must both be in a state of nature, for if not, lines of force must start from S and end at S_i , and others start at S_i and end at S , which is absurd.

If A were put to earth by means of a fine insulated wire passing through a tiny hole in B , and if B were insulated and charged with M units of electricity, we should have a charge x on S , a charge $-x$ on S_i , and a charge $M+x$ on S_o . To find x , we need only remember that $V_A = \frac{x}{r} - \frac{x}{r_i} + \frac{x}{r_o} + \frac{M}{r_o} = 0$, whence x may be obtained.

If B be put to earth, and A be connected by means of the fine wire just mentioned, with an electrical machine which keeps its prime conductor constantly at potential V_1 , A will receive a charge y and will be put at potential V_1 . To find y , it is to be noticed that there is a charge $-y$ on S_i , and no charge on S_o , which is put to earth. $V_A = \frac{y}{r} - \frac{y}{r_i} = V_1$, whence y may be obtained.

If $r = 99$ millimeters and $r_i = 100$ millimeters, $y = 9900 V_1$.

If a sphere, equal in size to A but having no shell about it, were connected with the same prime conductor, it too would receive a charge z sufficient to raise it to potential V_1 , and z would be determined by the equation $V_1 = \frac{z}{r}$. If $r = 99$, we have $z = 99 V_1$; hence we see that A , when surrounded by B at potential zero, is able to take one hundred times as great a charge from a given machine as it could take if B were removed. In other words, B increases A 's capacity one hundred fold. A and B together constitute what is called a *condenser*.

FIG. 42.

If A of the condenser AB , both parts of which are supposed uncharged, be connected by a fine wire (Fig. 42) with a sphere

A' which has the same radius as A , and is charged to potential V_1 , A and A' will now be at the same potential [V_2], and A will have the charge x , and A' the charge y . The total quantity of electricity on A' at first was rV_1 , so that $x + y = rV_1$, and

$$V_2 = \frac{y}{r} = \frac{x}{r} - \frac{x}{r_i} + \frac{x}{r_o},$$

whence x and y may be found.

The reader may study for himself the electrical condition of the different parts of two equal spherical condensers (Fig. 43),

FIG. 43.

of which the outer surface S_o of one is connected with an electric machine at potential V_1 , and the inside of the other, S'_i , is connected with the earth. The two condensers, which are supposed to be so far apart as to be removed from each other's influence, illustrate the case of two Leyden jars arranged in cascade.

63. Condensers made of Two Parallel Conducting Plates. Suppose two infinite conducting planes A and B to be parallel to each other at a distance a apart; choose a point of the plane A for origin, and take the axis of x perpendicular to the planes, so that their equations shall be $x = 0$ and $x = a$. Let the planes be charged and kept at potentials V_A and V_B respectively. It is evident from considerations of symmetry that the potential function at the point P between the two planes depends only upon P 's x coordinate, so that

$$D_y V = 0, \quad D_z V = 0, \quad D_y^2 V = 0, \quad D_z^2 V = 0.$$

Laplace's Equation gives, then,

$$D_x^2 V = 0,$$

whence $D_x V = C$, and $V = Cx + D$.

If $x = 0$, $V = V_A$; and if $x = a$, $V = V_B$; so that

$$V = (V_B - V_A) \frac{x}{a} + V_A, \text{ and } D_x V = \frac{V_B - V_A}{a}.$$

The lines of force are parallel between the planes, and the surface densities of the charges on A and B are

$$\frac{V_A - V_B}{4\pi a} \text{ and } \frac{V_B - V_A}{4\pi a} \text{ respectively.}$$

If we take a portion of area S out of the middle of each plate, there will be a quantity of electricity on S_A equal to $\frac{S(V_A - V_B)}{4\pi a}$, and an equal quantity of the other kind of electricity on S_B . The force of attraction between S_A and S_B will be $2\pi\sigma^2 \cdot S$, or

$$\frac{S}{8\pi} \frac{(V_B - V_A)^2}{a^2}.$$

If S_B be put to earth, the charge that must be given to S_A in order to raise it to potential unity is

$$\frac{S}{4\pi a}.$$

In other words, the capacity of S_A is inversely proportional to the distance between the plates.

In the case of two thin conducting plates placed parallel to and opposite each other, at a distance small compared with their areas, the lines of force are practically parallel except in the immediate vicinity of the edges of the plates;* and we may infer

FIG. 44.

* See Maxwell's *Treatise on Electricity and Magnetism*, Vol. I. Fig. XII.

from the results of this section that the capacity of a condenser consisting of two parallel conducting plates of area S , separated by a layer of air of thickness a , when one of its plates is put to earth is very approximately $\frac{S}{4\pi a}$ for large values of $\frac{S}{a}$.

64. Capacity of a Long Cylinder surrounded by a Concentric Cylindrical Shell. In the case of an infinite, conducting cylinder of radius r_i , kept at potential V_i and surrounded by a concentric conducting cylindrical shell of radii r_o and r' , kept at potential V_o , we have symmetry about the axis of the cylinder, so that $D_\phi V = 0$, and Laplace's Equation reduces to the form

$$D_r^2 V + \frac{D_r V}{r} = 0,$$

whence, for all points of empty space between the cylinder and its shell,

$$V = C + D \log r.$$

But $V = V_i$ when $r = r_i$, and $V = V_o$ when $r = r_o$,

hence
$$V = \frac{V_i \log \frac{r_o}{r} + V_o \log \frac{r}{r_i}}{\log \frac{r_o}{r_i}},$$
 [183]

and
$$D_r V = \frac{(V_o - V_i)}{\log \frac{r_o}{r_i}} \cdot \frac{1}{r}.$$

FIG. 45.

The surface densities of the electricity on the outer surface of the cylinder and the inner surface of the shell are respectively

$$\frac{V_i - V_o}{4\pi r_i \log \frac{r_o}{r_i}} \quad \text{and} \quad \frac{V_o - V_i}{4\pi r_o \log \frac{r_o}{r_i}},$$

so that the charge on the unit of length of the cylinder is $\frac{V_i - V_o}{2 \log \frac{r_o}{r_i}}$, and the charge on the corresponding portion of the

inner surface of the shell is the negative of this. We may find the capacity of the unit length of the cylinder by putting $V_o = 0$ and $V_i = 1$, whence capacity = $\frac{1}{2 \log \frac{r_o}{r_i}}$.

If r_o in this expression is made very large, the capacity of the cylinder will be very small.

In the case of a fine wire connecting two conductors, r_i will be very small, and there will be no conducting shell nearer than the walls of the room, so that the capacity of such a wire is plainly negligible.

65. Specific Inductive Capacity. In all our work up to this time we have supposed conductors to be separated from each other by electrically indifferent media, which simply prevent the passage of electricity from one conductor to another. We have no reason to believe, however, that such media exist in nature. Experiment shows, for instance, that the capacity of a given spherical condenser depends essentially upon the kind of insulating material used to separate the sphere from its shell, so that this material, without conducting electricity, modifies the action of the charges on the conductors. Insulators, when considered as transmitting electric action, are sometimes called *dielectrics*.

Whatever may really be the physical natures of the substances, such as glass, paraffine, ebonite, etc., which we commonly use as insulators, it has been shown that their behavior would be fairly well accounted for on the supposition that they

are made up of truly insulating matter in which are imbedded, at little distances from one another, small, conducting particles. It is evident that every such particle, if lying in a field of force, would be polarized; that is, one part would be charged positively by induction, and the part most remote from this would be charged negatively, and that these induced charges would have some influence in determining the values of the potential function at points in the dielectric and in the conductors adjacent to it.

Using the notation of Section 62, let the part A of a spherical condenser be charged with m units of positive electricity and separated from the part B , which is put to earth, by a spherical shell of radii r and r_1 made up of a given dielectric. Let us first ask ourselves what the effect of the dielectric would be if it consisted of extremely thin concentric conducting spherical shells separated by extremely thin insulating spaces. It is evident that in this case we should have a quantity $-m$ of electricity induced on the inside of the innermost shell, a quantity $+m$ on the outside of this shell, a quantity $-m$ on the inner surface of the next shell, a quantity $+m$ on the outside of this shell, and so on. If there were n such shells in the dielectric layer, and $n + 1$ spaces, and if δ were the distance from the inner surface of one shell to the inner surface of the next, and $\lambda\delta$ the thickness of each shell, the value, at the centre of A , of the potential function due to the charges on these shells, would be

$$V'_A = m \left[\frac{1}{r + \delta} - \frac{1}{r - \lambda\delta + \delta} + \frac{1}{r + 2\delta} - \frac{1}{r - \lambda\delta + 2\delta} \right. \\ \left. + \dots + \frac{1}{r + n\delta} - \frac{1}{r - \lambda\delta + n\delta} \right] \\ = -m\lambda\delta \left[\frac{1}{(r + \delta)(r - \lambda\delta + \delta)} + \frac{1}{(r + 2\delta)(r - \lambda\delta + 2\delta)} + \dots \right].$$

This quantity lies between

$$G = -m\lambda\delta \sum_{k=1}^{k=n} \frac{1}{(r + k\delta)^2} \quad \text{and} \quad H = -m\lambda\delta \sum_{k=0}^{k=n-1} \frac{1}{(r + k\delta)^2} :$$

but these differ from each other by less than $\epsilon = m\lambda\delta \frac{r_i^2 - r^2}{r^2 r_i^2}$, so that $-m\lambda \int_r^{r_i - (1-\lambda)\delta} \frac{dx}{x^2}$, which is easily seen to lie between G and H , differs from V_A' by less than ϵ . If, then, δ is very small in comparison with r and r_i , V_A' differs from $m\lambda \left(\frac{1}{r_i} - \frac{1}{r}\right)$ by an exceedingly small fraction of its own value.

This shows that the effect, at the centre of A , of such a system of conducting shells as we have imagined would be practically the same as if a charge $-m\lambda$ were given to the inner surface of the dielectric, and a charge $+m\lambda$ to its outer surface, while the charges on the surfaces of the thin shells within the mass of the dielectric were taken away. That is, the value of the potential function in A would be

$$m(1-\lambda) \left(\frac{1}{r} - \frac{1}{r'}\right) \text{ instead of } m \left(\frac{1}{r} - \frac{1}{r'}\right).$$

Such a system of shells introduced into what we have hitherto supposed to be the electrically inert insulating matter between the two parts of a spherical condenser would increase the capacity of the condenser in the ratio of 1 to $1-\lambda$. It is to be noticed that λ is a proper fraction: $\lambda=0$ and $\lambda=1$ would correspond respectively to a perfect insulator and to a perfect conductor.

As Dr. E. H. Hall has suggested to me, the result given above might be easily obtained by computing* the amount of work done in moving a unit particle of electricity (supposed to be concentrated at a point, and not to disturb existing distributions) from A to B . It is easy to see that the force at any point in the mass of one of the thin conducting shells would be zero, and that the force at any point in the space between two shells would be exactly the same as if there were no shells in the dielectric. We have no reason to think that there are any such differences between the values of the force at contiguous points in the dielectric as this would indicate, and the conception of the thin shells has been introduced only

* Mascart et Joubert, *Leçons sur l'Electricité*, § 124.

because the effect of these shells can be more easily computed than that of a number of discrete particles.

When, however, the dielectric between the parts of a spherical condenser is supposed to contain not a system of continuous shells, but a number of separate conducting particles, these are often regarded as forming a series of concentric layers, and it is assumed that the sum of the charges induced on the inner sides of the particles in the innermost layer is $-\lambda'm$, where λ' is a proper fraction, larger or smaller in different dielectrics according as the particles are nearer together or farther apart, and that the inner surfaces of all the other layers have each the same charge, and the outer surface of every layer the corresponding positive charge $+\lambda'm$. The effect of this kind of dielectric, if made to replace a perfect insulator in our calculations, would be to increase the capacity of the condenser in the ratio 1 to $1 - \mu$, where $\mu = \lambda'\lambda$, and it is evident that the same effect might be produced by a charge $-\mu m$ on that surface of the dielectric which touches A , and a charge $+\mu m$ on that surface which is in contact with B .

Experiment shows that dielectrics used to separate and to surround charged conductors behave, in many respects, as if every surface in contact with a conductor had a charge opposite in sign to that of the conductor, and in absolute value μ times as great, μ being less than unity, and constant for any one dielectric. That is, if the dielectric separating from each other a number of conductors be displaced by another, the capacities of all the conductors will be changed in the same ratio, depending only upon the natures of the two dielectrics.

The ratio of the fraction $\frac{1}{1 - \mu}$, in the case of any dielectric to the same fraction in the case of air, for which μ is very nearly the same as for what we call a vacuum, is called the *specific inductive capacity* of the dielectric in question. This ratio is greater than unity for all solid and liquid dielectrics with which we are acquainted. The specific inductive capacity of a perfect conductor would be infinite.

The following very clear statement of the effect produced by changing the dielectric which envelops the parts of a condenser made of two plates, is due to Dr. Hall, and is copied with his permission :

“The fundamental fact concerning static electrical induction as observed by Faraday is this,* that if the two plates of a condenser, separated by air, receive respectively e_1 and $-e_2$ units of electricity when charged to a certain difference of potential, *e.g.*, by connection with the poles of a battery of many cells in series, the same two plates would, if any other medium were substituted for the air, other conditions remaining unchanged, receive respectively Ke_1 and $-Ke_2$ units of electricity, K being some quantity greater than unity. This quantity K is called the specific inductive capacity of the second medium.

“Now, since the difference of potential between A and B is the same in these two cases, the ‘electromotive intensity,’ † *i.e.*, the force exerted upon unit quantity of electricity, is the same in the two cases at any given point lying in the region through which the change of dielectric extends. If we were to attempt to determine the surface densities of the charges of the conductors by means of the equation ‡

$$\frac{dV_2}{dv} - \frac{dV_1}{dv} + 4\pi\sigma' = 0,$$

the values obtained would be the same for both cases. These would be the actual values of the surface densities if air were used, but would evidently not be the actual surface densities for the other case. For this latter case, the values thus found are called the ‘*apparent*’ surface densities, and bear to the true densities the ratio 1 to K .

“We must not conclude from this that A and B with charges Ke_1 and $-Ke_2$ respectively in the second medium would act,

* Maxwell’s *Treatise on Electricity and Magnetism*, Art. 52.

† Maxwell’s *Treatise on Electricity and Magnetism*, Art. 44.

‡ Maxwell’s *Treatise on Electricity and Magnetism*, First Edition, Art. 83.
See, also, Section 47 of this book.

in *all* electrical respects, like the same bodies with charges e_1 and $-e_2$ in air. Two spheres, A and B , in air, with centres at distance r from each other, and having charges e_1 and $-e_2$ respectively, would attract each other with a force $\frac{e_1 e_2}{r^2}$, whereas the same two spheres with actual charges Ke_1 and $-Ke_2$ in a medium of specific inductive capacity K would attract each other with a force* $\frac{Ke_1 e_2}{r^2}$. This seems at first inconsistent with the fact that the electromotive intensity at any point, as stated above, is the same in both cases. The electromotive intensity at any point, however, means the force that would be exerted upon unit *actual* quantity of electricity at that point, not the force that would be exerted upon unit *apparent* quantity. So the average force exerted by A 's charge upon B 's charge in either of our two cases is $\frac{e_1}{r^2}$ for each actual unit of B 's charge. Hence, the total force exerted by A upon B is $\frac{e_1 e_2}{r^2}$ for the first case, and $\frac{Ke_1 e_2}{r^2}$ for the second case, as stated before."

66. Charge induced on a Sphere by a Charge at an Outside Point. The value at any point P of the potential function due to m_1 units of positive electricity concentrated at a point A_1 , and m_2 units of negative electricity concentrated at a point A_2 , is

$$V = \frac{m_1}{r_1} - \frac{m_2}{r_2} \quad \text{where} \quad r_1 = A_1 P \quad \text{and} \quad r_2 = A_2 P.$$

It is easy to see that if m_1 is greater than m_2 , so that $m_1 = \lambda m_2$ where $\lambda > 1$, V will be equal to zero all over a certain sphere which surrounds A_2 .

If (Fig. 46) we let $A_1 A_2 = a$, $A_1 O = \delta_1$, $A_2 O = \delta_2$, $OD = r$, it is easy to see that

$$\delta_1 = \frac{\lambda^2 a}{\lambda^2 - 1}, \quad \delta_2 = \frac{a}{\lambda^2 - 1}, \quad r^2 = \frac{a^2 \lambda^2}{(\lambda^2 - 1)^2} = \delta_1 \delta_2, \quad \lambda^2 = \frac{\delta_1}{\delta_2},$$

* Maxwell's *Treatise on Electricity and Magnetism*, Art. 94.

and
$$a = \frac{\delta_1^2 - r^2}{\delta_1} = \frac{r^2 - \delta_2^2}{\delta_2}. \quad [176]$$

If PR represents the force f_1 due to the electricity at A_1 , and PQ the force f_2 due to the electricity at A_2 , the line of action of the resultant force F (represented by PL) must pass through the centre of the sphere, since the surface of the sphere is equipotential.

FIG. 46.

The triangles A_1PO and A_2PO are mutually equiangular, for they have a common angle A_1OP , and the sides including that angle are proportional ($r^2 = \delta_1\delta_2$). Hence, from the triangles QPL and A_1PA_2 , by the Theorem of Sines,

$$\frac{f_1}{\sin a_1} = \frac{f_2}{\sin a_2} = \frac{F}{\sin(a_2 - a_1)}, \quad [177]$$

$$\frac{r_1}{\sin a_2} = \frac{r_2}{\sin a_1} = \frac{a}{\sin(a_2 - a_1)}, \quad [178]$$

whence
$$F = \frac{af_1}{r_2} = \frac{am_1}{r_2 r_1^2} = \frac{a\lambda m_1}{r_1^3}. \quad [179]$$

Now, according to Section 50, we may distribute upon the spherical surface just considered a quantity m_2 of negative electricity in such a way that the effect of this distribution at all points outside the sphere shall be equal to the effect of the charge $-m_2$ concentrated at A_2 , and the effect at points within the sphere shall be equal and opposite to the effect of the charge m_1 concentrated at A_1 . Since F is the force at P in the direc-

tion of the interior normal to the sphere, we shall accomplish this if we make the surface density at every point equal to σ , where

$$4\pi\sigma = -F = \frac{-\alpha\lambda m_1}{r_1^3} = \frac{-(\delta_1^2 - r)^2 m_1}{r r_1^3}; \quad [180]$$

and if we now take away the charge at A_2 , the value of the potential function throughout the space enclosed by our spherical surface, and upon the surface itself, will be zero. If the spherical surface were made conducting, and were connected with the earth by a fine wire, there would be no change in the charge of the sphere, and we have discovered the amount and the distribution of the electricity induced upon a sphere of radius r , connected with the earth by a fine wire and exposed to the action of a charge of m_1 units of positive electricity concentrated at a point at a distance δ_1 from the centre of the sphere.

If now we break the connection with the earth, and distribute a charge m uniformly over the sphere in addition to the present distribution, the potential function will be constant (although no longer zero) within the sphere, and we have a case of equilibrium, for we have superposed one case of equilibrium (where there is a uniform charge on the sphere and none at A_1) upon another. The whole charge on the sphere is now

$$M = m - m_2 = m - \frac{m_1 r}{\delta_1},$$

and the value of the potential function within it and upon the surface,

$$V = \frac{M}{r} + \frac{m_1}{\delta_1} = \frac{m}{r}.$$

If the conducting sphere were at the beginning insulated and uncharged, we should have $M = 0$, and therefore

$$\sigma = \frac{m_1}{4\pi r} \left(\frac{1}{\delta_1} - \frac{\delta_1^2 - r^2}{r_1^3} \right), \quad \text{and} \quad V = \frac{m_1}{\delta_1}. \quad [181]$$

If we have given that the conducting sphere, under the influence of the electricity concentrated at A_1 is at potential V_1 , we

know that its total charge must be $V_1 r - \frac{m_1 r}{\delta_1}$, and its surface density

$$= \frac{1}{4 \pi r} \left(V_1 - \frac{(\delta_1^2 - r^2) m_1}{r_1^3} \right). \quad [182]$$

It is easy to see that the sphere and its charge will be attracted toward A_1 with the force

$$\frac{m_1 r}{\delta_1} \left(\frac{m_1 \delta_1^2}{(\delta_1^2 - r^2)^2} - \frac{V_1}{\delta_1} \right); \quad [183]$$

and the student should notice that, under certain circumstances, this expression will be *negative* and the force repulsive.

If $m_1 = m_2$, the surface of zero potential is an infinite plane, and our equations give us the charge induced on a conducting plane by a charge at a point outside the plane.

The method of this section enables us to find also the capacity of a condenser composed of two conducting cylindrical surfaces, parallel to each other, but eccentric; for a whole set of the equipotential surfaces due to two parallel, infinite straight lines, charged uniformly with equal quantities per unit of length of opposite kinds of electricity, are eccentric cylindrical surfaces surrounding one of the lines A_2 , and leaving the other line A_1 outside. We may therefore choose two of these surfaces, distribute the charge of A_1 on the outer of these, and the charge of A_2 on the inner, by the aid of the principles laid down in Section 50, so as to leave the values of the potential function on these surfaces the same as before. These distributions thus found will remain unchanged if the equipotential surfaces are made conducting.

The reader who wishes to study this method more at length should consult, under the head of Electric Images, the works of Cumming, Maxwell, Mascart, and Watson and Burbury, as well as original papers on the subject by Murphy in the *Philosophical Magazine*, 1833, p. 350, and by Sir W. Thomson in the *Cambridge and Dublin Mathematical Journal* for 1848.

67. The Energy of Charged Conductors. If a conductor of capacity C , removed from the action of all electricity except its own, be charged with M_1 units of electricity, so that it is at potential $V_1 = \frac{M_1}{C}$, the amount of work required to bring up to the conductor, little by little, from the walls of the room, the additional charge ΔM , is ΔW , which is greater than $V_1 \cdot \Delta M$ or $\frac{M_1}{C} \cdot \Delta M$, and less than $(V_1 + \Delta_x V) \cdot \Delta M$ or $\frac{M_1 + \Delta M}{C} \cdot \Delta M$.

If the charge be increased from M_1 to M_2 by a constant flow, the amount of work required is evidently

$$\int_{M_1}^{M_2} \frac{M dM}{C} = \frac{M_2^2 - M_1^2}{2C} = \frac{C}{2} (V_2^2 - V_1^2). \quad [184]$$

The work required to bring up the charge M to the conductor at first uncharged is then

$$\frac{M^2}{2C} = \frac{CV^2}{2} = \frac{MV}{2}. \quad [185]$$

This is evidently equal to the potential energy of the charged conductor, and this is independent of the method by which the conductor has been charged.

If, now, we have a series of conductors A_1, A_2, A_3 , etc., in the presence of each other at potentials V_1, V_2, V_3 , etc., and having respectively the charges M_1, M_2, M_3 , etc., and if we change all the charges in the ratio of x to 1, we shall have a new state of equilibrium in which the charges are xM_1, xM_2, xM_3 , etc.; and the values of the potential functions within the conductors are xV_1, xV_2, xV_3 , etc. The work (ΔW) required to increase the charges in the ratio $x + \Delta x$ instead of in the ratio x is greater than

$$(M_1 \Delta x) (xV_1) + (M_2 \Delta x) (xV_2) + (M_3 \Delta x) (xV_3) + \text{etc.},$$

or $x \Delta x [M_1 V_1 + M_2 V_2 + M_3 V_3 + \text{etc.}],$

and less than

$$(x + \Delta x) \Delta x [M_1 V_1 + M_2 V_2 + M_3 V_3 + \text{etc.}];$$

hence the whole amount of work required to change the ratio from $\frac{x_1}{1}$ to $\frac{x_2}{1}$ is

$$W_2 - W_1 = \frac{x_2^2 - x_1^2}{2} [M_1 V_1 + M_2 V_2 + M_3 V_3 + \text{etc.}]. \quad [186]$$

If in this equation we put $x_1 = 0$ and $x_2 = 1$, we get for the work required to charge the conductor from the neutral state to potentials $V_1, V_2, V_3,$

$$W = \frac{1}{2} [M_1 V_1 + M_2 V_2 + M_3 V_3 + \dots] = \frac{1}{2} \sum (\dot{M}V). \quad [187]$$

68. If a series of conductors $A_1, A_2, A_3,$ etc., are far enough apart not to be exposed to inductive action from one another, and have capacities $C_1, C_2, C_3,$ etc., and charges $M_1, M_2, M_3,$ etc., so as to be at potentials $V_1, V_2, V_3,$ etc., where $M_1 = C_1 V_1, M_2 = C_2 V_2, M_3 = C_3 V_3,$ etc., we may connect them together by means of fine wires whose capacities we may neglect, and thus obtain a single conductor of capacity

$$C_1 + C_2 + C_3 + \dots = \sum (C).$$

The charge on this composite conductor is evidently

$$M_1 + M_2 + M_3 + \dots = \sum (M);$$

and if we call the value of the potential function within it V , we shall have

$$V \cdot \sum (C) = \sum (M);$$

whence
$$V = \frac{C_1 V_1 + C_2 V_2 + C_3 V_3 + \dots}{C_1 + C_2 + C_3 + \dots}, \quad [188]$$

a formula obtained, it is to be noticed, on the assumption that the conductors do not influence each other.

The energy of the separate charged conductors before being connected together was

$$\begin{aligned} W &= \frac{1}{2} (M_1 V_1 + M_2 V_2 + M_3 V_3 + \dots) = \frac{1}{2} \left(\frac{M_1^2}{C_1} + \frac{M_2^2}{C_2} + \frac{M_3^2}{C_3} + \dots \right) \\ &= \frac{1}{2} \sum \left(\frac{M^2}{C} \right), \end{aligned} \quad [189]$$

and the energy of the composite conductor is

$$\begin{aligned}
 W' &= \frac{\frac{1}{2}(M_1 + M_2 + M_3 + \dots)(C_1 V_1 + C_2 V_2 + C_3 V_3 + \dots)}{C_1 + C_2 + C_3 + \dots} \\
 &= \frac{\frac{1}{2}(M_1 + M_2 + M_3 + \dots)^2}{C_1 + C_2 + C_3 + \dots} = \frac{\frac{1}{2} \left[\sum (M) \right]^2}{\sum (C)}, \quad [190]
 \end{aligned}$$

which is always less than E unless the separate conductors were all at the same potential in the beginning.

69. Steady Currents of Electricity. As we have already seen,* when a charged body A is brought up into the neighborhood of a previously uncharged, insulated conductor B , the two kinds of electricity which, according to our provisional theory, exist in equal quantities in every particle of B , tend to separate from each other and, as a consequence, free electricity appears on B 's surface; some parts of this surface becoming charged positively and other parts negatively. If A is brought into a given position and fixed there, the distribution on the surface of B quickly attains and keeps — except as there may be leakage into the surrounding medium — a value determined by the fact that the whole interior of B must be a region at constant potential, or, in other words, that the resultant force at any point within B due to the free electricities on its surface must be equal and opposite to the force at that point due to all the free electricity outside B . If now A with its charge is moved to a new position, the old distribution on B 's surface will not in general screen the interior of B from the action of A 's charge, and a new separation of electricity within B and a new arrangement or combination of the charge on the surface is necessary before a new state of equilibrium can be established. If A be moved continuously in any manner, there will be a constant attempt on the part of the separated electricities to set

* See Section 53.

up a state of equilibrium, and hence at every point of B there will be, in general, some electrical change going on continually.

If two conductors A and B at different potentials be connected by a fine wire, the whole will form a single conductor, which can only be in a state of equilibrium when the value of the potential function due to all the free electricity in existence is constant throughout its interior, and there will be such a transfer of electricity through the wire as will establish this state of equilibrium in a very short time. If, however, by any device we can furnish unlimited quantities of electricity to A and B in such a way as to keep them at the same potentials as at the beginning, there will be a continual attempt to establish electric equilibrium within the compound conductor consisting of A , B , and the wire, and, as a result, there will be a continual transfer of electricity through the wire.

The transfer of electricity from one place to another through a conductor is a very common phenomenon. Sometimes, as we have seen, electricity traverses the conductor for a short time only; sometimes, however, the transfer goes on indefinitely, and, so far as we can judge from its attendant phenomena, at a constant rate, so that just as much of a given kind of electricity crosses any surface within the conductor in any one second as in any other: such a continuous steady transfer as this is called a "steady current."

The existence of a steady current in a conductor implies a force tending to drive electricity through the conductor; that is, it implies, at least in the absence of moving magnetic masses and of electric currents in the neighborhood of the conductor, free electricity somewhere in existence which gives rise to a potential function not constant throughout the conductor. No part of a conductor through which a steady current is flowing can accumulate free electricity as the time goes on, for such an accumulation increasing with the time would be accompanied by changes which must show themselves outside the conductor. We are led to assume, then, that if any closed surface be drawn inside a conductor which carries a steady current, just as much

electricity of a given kind enters the region enclosed by the surface in any interval of time as leaves it during that interval.

We have seen that at every point inside a conductor where there is a resultant electric force there will be an electric separation which will go on as long as the force exists. Experiment seems to show that the rate of separation of quantities of electricity is proportional to the magnitude of the force. Let P be a point of a small plane area ω inside a conductor, and let F be the average value during the interval from t to $t + \Delta t$ of the component of the electric force normal to this area; then in what follows we shall assume that the amount of positive electricity which crosses this surface, in the sense in which the force points, during the interval is $k \cdot \omega \cdot F \cdot \Delta t$, where k is a constant depending only upon the material of which the conductor is composed and upon its physical condition. The average value of this flux per unit of time per unit of surface is, therefore, $k \cdot F$. If, now, ω and Δt are made to grow smaller and smaller in such a manner that P is always a point of ω , F approaches as a limit the negative of the value at P of the derivative, taken in the direction in which F acts, of V , the potential function due to all the free electricity in existence; so that at any instant the value at a point, P , in any direction, n , of the rate of flow of positive electricity across a surface normal to n , per unit of this surface per unit of time, is the value at P of $-k \cdot D_n V$.

It follows from this that if any tube of force be drawn in a conductor which carries a steady current, there is no flow through the sides of the tube. Consider a region shut in by a tube of force and by two equipotential surfaces inside a conductor through which a steady current is flowing. Let ω_1 and ω_2 be the areas of the equipotential ends of the region, and let F_1 and F_2 be the average values of the normal force, taken in the same sense in both cases, over these ends. Applying Gauss's theorem to this region we have $F_2 \omega_2 - F_1 \omega_1 = 4\pi Q$, where Q is the amount of free electricity, algebraically considered, within the region. If the conductor is homogeneous, the amount of

positive electricity which enters — or the amount of negative electricity which leaves — the region by one end per unit of time is $kF_1 \cdot \omega_1$, and the amount which leaves it at the other end is $kF_2 \cdot \omega_2$. These amounts are equal, so that $F_2\omega_2 - F_1\omega_1 = 0$; hence, $Q = 0$, and there is no free electricity at any point within a homogeneous conductor which carries a steady current. The free electricity which gives rise to the potential function the rate of change of which is proportional to the flow of electricity within the conductor, must then lie either outside the conductor, or on its surface, or both. It would not be difficult to prove that there must be a distribution of electricity on parts of the surface of every conductor which carries a steady current and is in contact in some places with an insulating medium; but the fact that a wire through which such a current is passing may be moved about so as to change its position with respect to outside bodies without changing the amount of the current will suffice to make it probable that a part, at least, of the free electricity that we have been considering moves with the wire. Since the density of the free electricity within a conductor which carries a steady current is zero, the potential function V , inside the conductor, must satisfy Laplace's Equation; that is, $\nabla^2 V = 0$. It is easy to see, since there can be no accumulation of free electricity in any conductor which bears a steady current, that the amount of electricity which comes up on one side to the common surface of two such conductors which are in contact must be equal to that which goes away from this surface on the other; that is, at every point of the surface, $k_1 \cdot D_n V_1 = k_2 \cdot D_n V_2$, where k_1 and k_2 are the specific conductivities of the two conductors, and $D_n V_1$ and $D_n V_2$ the values at the point, taken in the same sense in both cases, of the derivatives of V in the direction of the normal to the surface, one on one side of the surface, and the other on the other. It is to be noticed that the boundary between two such conductors may or may not be an equipotential surface. At every point of the common surface of a conductor and an insulating medium $k \cdot D_n V = 0$ or $D_n V = 0$; hence the equipotential sur-

faces within the conductor cut the surface where the conductor abuts on the insulating medium at right angles.

70. Linear Conductors. Resistance. Law of Tensions. Let us consider the case of a linear conductor, that is, one in which all the lines of force are parallel to each other and to the sides of the conductor, so that every tube of force has a constant cross-section throughout that part of its length which lies in the given conductor. It will appear later on that any right cylindrical conductor, whatever the form of its cross-section, will be a linear conductor, if every point of one of its ends be kept at one constant potential, and every point of the other end at another. It will also be evident that such wires as are ordinarily used for making electrical connections are, to all intents and purposes, except perhaps at the very ends, linear conductors, whether these wires are straight or curved. Let the ends of a homogeneous long uniform straight wire of constant cross-section q , and of length l , be kept respectively at potentials V' and V'' . Take the axis of the wire for the axis of x , and the origin at that end of the wire at which the potential function due to all the free electricity in existence is V' ; then every line of force inside the wire is parallel to the axis of x ; and since there is no force in any direction perpendicular to the axis of x , $D_y V = 0$, $D_z V = 0$, and Laplace's Equation, which must be satisfied by V inside the wire becomes $D_x^2 V = 0$, whence $V = Ax + B$; or, since $V = V'$ when $x = 0$, and $V = V''$ when $x = l$,

$$V = \frac{(V'' - V')x}{l} + V'.$$

The steady current c which traverses the wire carries across every right section in the unit of time $-kq \cdot D_x V$ units of positive electricity in the positive direction of the axis of x . That is,

$$c = -kq \cdot D_x V = \frac{kq}{l}(V' - V''),$$

where k is the specific conductivity of the material out of which

the wire is made. The quantity $\frac{l}{kq}$ is called the *resistance* of the wire, the quantity $\frac{kq}{l}$ its *conductivity*. The quantity k is a function of the temperature. In the case of a pure solid metal at any ordinary temperature a rise of 10° Centigrade will increase $\frac{1}{k}$ by something like $\frac{1}{27}$ th of its own value. This fractional increase is much smaller in the case of some alloys: for German silver it is about $\frac{1}{227}$.

It is an important physical principle, first enunciated in a slightly different form by Ohm, that if a fixed portion of the surface of a given homogeneous conductor be kept constantly at potential V_1 , and another fixed portion at potential V_2 , while the rest of the surface of the conductor is in contact with an insulating medium, the ratio of $V_1 - V_2$ to the steady current which traverses the conductor, — as measured by the quantity of positive electricity per unit of time which either enters the conductor through the surface $V = V_1$ or leaves it through the surface $V = V_2$, — is a quantity independent of V_1 and V_2 . This ratio is called the resistance of the conductor under the given circumstances. The resistance of a conductor depends not only upon its shape, the material of which it is composed, and the temperature and other physical conditions of this material, but also upon the shape, size, and position of those portions of the surface which are kept at the potentials V_1 and V_2 . The resistance of so much of a tube of force drawn in a conductor which bears a steady current as lies between the equipotential surfaces $V = V_1$ and $V = V_2$ is the ratio of $V_1 - V_2$ to the amount of positive electricity per unit of time which enters the portion of the tube which we have been considering through the surface $V = V_1$, or leaves it through the surface $V = V_2$, or crosses any section of the tube in the direction indicated. Any electric change which, under the same conditions of temperature and pressure, will leave this tube of force still

a tube of force and its equipotential ends still equipotential, however the value of the potential function may be changed, will, according to this law of Ohm, leave the resistance the same. Other things being equal, the resistance of a tube of force increases with the length of the tube and diminishes as the section of the tube is made greater.

Suppose that we have a series of linear conductors joined end to end in a closed ring, so that the end of the n th conductor is in contact with the beginning of the first. Let V_m' and V_m'' be the values of the potential function at the beginning and end of the m th conductor, and r_m the resistance of this conductor. Since the same current c must traverse every conductor of the series, we have

$$V_1' - V_1'' = cr_1, V_2' - V_2'' = cr_2, V_3' - V_3'' = cr_3, \dots V_n' - V_n'' = cr_n;$$

and, if we add them together, we shall get

$$c = \frac{(V_2' - V_1'') + (V_3' - V_2'') + (V_4' - V_3'') + \dots + (V_1' - V_n'')}{r_1 + r_2 + r_3 + \dots + r_n},$$

where $V_2' - V_1''$ is the difference between the values of the potential function on opposite sides of the surface common to the second and first conductors, $V_3' - V_2''$ the corresponding difference for the third and second conductors, and so on around the ring.

Experiment shows that when any two conductors made of different materials are placed in contact with each other, a sudden separation of electricity takes place at the common surface,* and there is set up a difference of potential between them which gives rise to a discontinuity of the potential function at the

* Although the language of the old "Two Fluid Theory" is used in this chapter, the reader is strongly urged to make himself acquainted with the physical theories now commonly used in accounting for electrical phenomena. See Dr. O. J. Lodge's papers "On the Seat of the Electromotive Force in the Voltaic Cell," printed in the *Philosophical Magazine* for March, April, May, and October of 1885, and his "Modern Views of Electricity," a series of contributions to *Nature*, begun in 1886.

surface. The amount of this discontinuity, which remains constant after it has once been established, is the same for all points of the common boundary of the two conductors, and is independent of their size and shape, of the extent of surface in contact, and of the absolute values of the potential function on either side of the boundary. We shall represent the sudden fall in the value of the potential function encountered by passing from a conductor made of material A to a conductor made of material B across any point of their common surface by the symbol $A | B$. A certain class of substances, to which all metals belong, has the property that if L , M , and N are any three of these substances, all at the same temperature,

$$L | M + M | N = L | N.$$

This class is said to obey "Volta's Law of Tensions." If a number of conductors made of different kinds of metals all at the same temperature be placed in line; the first in contact with the second, the second with the third, and so on, the algebraic sum of the jumps of the potential function encountered in going from the first conductor to the last through all the others is exactly the same in amount as the single jump which would occur at the common surface of the first and last conductors if they were put directly in contact with each other. Some other substances besides metals obey the Law of Tensions, but most liquids and solutions, whether in contact with each other or with metals, do not obey this law.

The sum of the jumps in the potential function encountered in passing from copper to zinc by way of an iron conductor is the same, if the whole be at one temperature, as the jump encountered in passing directly from copper to zinc. But this is not equal to the sum of the jumps met with in passing from copper to zinc through sulphuric acid.

$$\begin{array}{l} \text{Cu} | \text{Fe} + \text{Fe} | \text{Zn} = \text{Cu} | \text{Zn}, \\ \text{but} \quad \text{Cu} | (\text{H}_2\text{SO}_4) + (\text{H}_2\text{SO}_4) | \text{Zn} \neq \text{Cu} | \text{Zn}. \end{array}$$

The numerator of the expression just found for the intensity of the current which traverses a closed chain of linear conduc-

tors is evidently the algebraic sum of the jumps in the potential function encountered by travelling in the direction in which the current is supposed to move; *i.e.*, from the first conductor to the last through all the others, and reckoning the jump at any boundary positive if the value of the potential function is increased as one crosses the boundary. If all the conductors which form the circuit are metallic and all at the same temperature, whether or not they are all made of the same kind of metal, this numerator is zero, and it follows that in order that a steady current may traverse a circuit of conductors, one at least of the conductors must not obey the Law of Tensions.

The same formulas apply to a circuit composed of conductors of any form if each of the common surfaces of contiguous conductors is equipotential.

71. Electromotive Force. A galvanic battery may be regarded as a chain of three or more generally non-linear conductors, at least one of which disobeys the Law of Tensions. The first and last members of the chain are called the poles of the battery. The algebraic sum of the jumps in the potential function encountered by starting at that pole of a galvanic battery at which the potential is less, and passing to the other pole through the battery, is called the electromotive force of the battery. The difference of potential between the poles of the battery, when they are not connected, measures this electromotive force. Chemical action goes on inside every battery when its poles are closed; some of its solutions are decomposed, and the products of this decomposition often appear at the boundaries of the liquid conductors inside the battery, and decrease the electromotive force by changing the amount of jump in the potential function at each of these boundaries. For this reason the electromotive force of a battery in action may be much less than when the poles are open. This difference, when the poles are closed by a conductor of low resistance, often amounts to 40 per cent of the whole in the case of a Daniell's cell, and to much more in the case of a less constant element.

It is easy to show that when the poles of a battery are closed by a conductor of resistance R , the difference between the values of the potential function at the ends of this conductor is $\frac{RE}{B+R}$, where E is the electromotive force of the battery under the given circumstances, and B the resistance of the conductors which make up the battery itself.

The steady current which flows through the circuit carries $\frac{E}{B+R}$ units of positive electricity across every cross-section per unit of time. With a given battery the intensity of the current can be changed very much by increasing or decreasing the resistance of that part of the circuit which lies outside the battery.

In dealing with problems in electrostatics, we have assumed that the units have been so chosen that the unit quantity of positive electricity concentrated at a point would repel a like quantity at the unit distance from the first with the unit force. With this understanding, our formulas are correct whatever the absolute values of the units may be. If, however, the units are such that the unit quantity of electricity concentrated at a point repels a like quantity at the unit distance from the first, with μ times the unit of force, the quantity μ will enter as a factor into most of our formulas.

In the Centimetre-gramme-second system of Electrostatic Absolute Units the unit of electric quantity is that quantity of electricity which, if it could be concentrated at a point, would repel a like quantity concentrated at a point a centimetre from the first with a force of one dyne. This unit is found inconveniently small, however, when one has to deal with such steady currents as are usually met with in practice, and the coulomb,* which is equal to about 3,000,000,000 of these absolute units, is the practical unit of quantity most frequently used. The prac-

* This unit is one-tenth of what is called the Centimetre-gramme-second Absolute Electromagnetic Unit of Quantity.

tical unit of resistance, called the ohm, is the resistance of a column of pure mercury, one square millimetre in section and one hundred and six centimetres long, at zero degrees Centigrade.*

The unit of difference of potential, called the volt, is such that if the two ends of a wire of one ohm resistance were kept at a volt's difference of potential, the steady current which traversed the wire would carry past any cross-section a coulomb of electricity per second. The electromotive force of a carefully set up Daniell's cell is about 1.08 volts.

A current of a coulomb per second is called an ampere. A condenser which requires one coulomb of electricity to charge it so that the difference of potential between its poles is one volt, is said to have a capacity of one farad. The practical unit of capacity is the microfarad or the millionth of a farad. The capacity of a conducting sphere nine kilometres in radius would be one microfarad, that of the earth something over 700 microfarads. The capacity of a nautical mile of such ocean telegraph cable as is usually laid may be taken to be about one-third of a microfarad.

72. Kirchhoff's Laws. The Law of Divided Circuits. From what has been proved in the preceding sections about conductors which carry steady currents follow two theorems of much practical importance, called Kirchhoff's Laws.

I. If several wires which form part of a conductor carrying a steady current meet at a point, the sum of the intensities of all the currents which flow towards the point through the wires is equal to the sum of all those which recede from it; or, in other words, the algebraic sum of all the currents which approach the point through the compound conductor is zero.

II. If out of any network of wires which form a complex conductor and carry a steady current a number of wires which form a closed figure be chosen, and if, starting at any point,

* The resistance at 0° Centigrade of a wire of pure copper 1^{mm} in diameter and 1^m long is about 0.01642 ohms.

we follow the figure around in either direction, calling all currents which move with us positive, and all discontinuities of the potential function which lift us from places of lower potential to places of higher potential positive, the algebraic sum of the products formed by multiplying the resistance of each conductor by the current running through it is equal to the algebraic sum of the jumps in the potential function which we encounter in going completely around the figure.

The first of these laws is an immediate consequence of the fact that there can be no growing accumulation of free electricity anywhere in a circuit which bears a steady current. To prove the second law, let $a_1, a_2, a_3 \dots a_n$, be n linear conductors, which, taken in order, form a closed figure, itself a part of a complex conductor which carries a steady current. In passing from a_1 to a_n through all the other conductors, let V_j' and V_j'' be the values of the potential function at the beginning and end of the j th conductor, and let r_j and c_j be respectively the resistance of this conductor and the value of the current running through it. Then, from the definition of the term resistance, we have the following equations :

$$\begin{aligned} V_1' - V_1'' &= c_1 r_1; & V_2' - V_2'' &= c_2 r_2; \\ V_3' - V_3'' &= c_3 r_3; & \dots & V_n' - V_n'' = c_n r_n; \end{aligned}$$

or, adding them all together,

$$\begin{aligned} c_1 r_1 + c_2 r_2 + c_3 r_3 + \dots + c_n r_n \\ = V_2' - V_1'' + V_3' - V_2'' + V_4' - V_3'' + \dots + V_1' - V_n'', \end{aligned}$$

which is the statement of this law.

If electricity is free to pass from a point P to another point P' by two wires of resistance r_1 and r_2 respectively, and if a steady current be flowing from P to P' , the current will be divided between the two wires in the inverse ratio of their resistances or in the direct ratio of their conductivities.

For, if V and V' be the values of the potential function at P and P' , we have $V - V' = c_1 r_1$ and $V - V' = c_2 r_2$, whence $c_1 : c_2 = r_2 : r_1$.

Moreover,
$$c_1 + c_2 = (V - V') \left(\frac{1}{r_1} + \frac{1}{r_2} \right);$$

or,
$$\frac{V - V'}{c_1 + c_2} = \frac{1}{\frac{1}{r_1} + \frac{1}{r_2}}.$$

The expression in the second number of the last equation is, by the definition of the term, the resistance of the compound conductor formed of the two which join P and P' . It is evident that the conductivity of this conductor is the sum of the conductivities of the two wires of which it is composed.

Almost all the formulas commonly used in the laboratory in comparing resistances, electromotive forces, and capacities can be deduced from the theorems proved in this section, and although it lies entirely beyond the scope of this book to consider methods of making electric measurements, applications of these theorems to a few examples, the importance of which will be appreciated only by those who have studied the subject elsewhere, are subjoined by way of illustration.

I. WHEATSTONE'S BRIDGE.

If four wires, AB , BD , DF , FA , having resistances R_1 , R_2 , R_4 , R_3 , respectively, form a closed quadrilateral, and if the

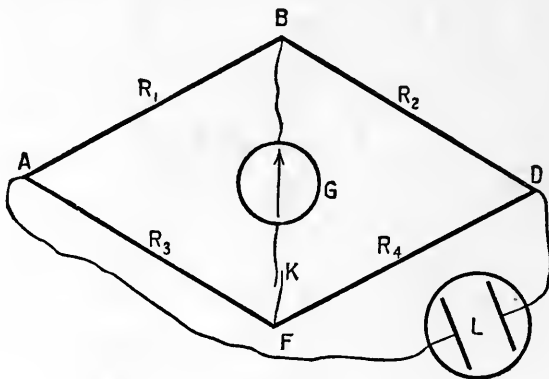

FIG. 47.

poles of a battery be joined to two opposite vertices A and D of the figure, and the connecting wires of a galvanometer, or

other instrument for detecting the existence of a current, to the other two vertices, then if the galvanometer shows no current, $R_1 : R_2 = R_3 : R_4$.

To prove this, let C_1, C_3, C_2, C_4 , be the currents which flow in the direction indicated by the order of the letters used in naming the wires, in AB, AF, BD , and FD , respectively.

Applying Kirchoff's First Law to the points B and F , we get $C_1 = C_2$ and $C_3 = C_4$. Applying the Second Law to $ABGF$ and $DBGF$ successively, we have $C_1 R_1 = C_3 R_3$, $C_2 R_2 = C_4 R_4$; whence, dividing the last of these equations by the preceding one and equating C_1 to C_2 and C_3 to C_4 , we have the required relation.

If AB and BD are two wires whose resistances we wish to compare, we may arrange them as in the diagram and use for AFD a long piece of uniform wire. We may then slide F along on this wire until depressing the key K in the galvanometer branch causes no current to go through the latter. When this point has been found, the *lengths* of the segments of the wire AFD are to each other as the resistances of AB and BD .

II. POGGENDORFF'S METHOD OF COMPARING ELECTROMOTIVE FORCES.

The electromotive force of an element may be compared with that of a more powerful battery whose internal resistance is known by a method due originally to Poggendorff. Join up

FIG. 48.

the batteries as in the accompanying diagram with their electromotive forces opposed, and alter the resistance R of the

branch AD until the galvanometer G shows no current; then the electromotive force of the element, L' , is to the electromotive force of the battery, or element, L , as R is to the whole resistance in the circuit $ADLA$.

Let B be the resistance of the branch ALD , and apply Kirchoff's Second Law to the closed figures $ADL'A$ and $ADLA$. Since no current passes through G , we have $CR = E'$ and $C(B + R) = E$, where C is the current which traverses the circuit $ADLA$. Eliminating C from these equations, we have

$$E' : E = R : B + R. \quad \text{Q.E.D.}$$

III. THOMSON'S METHOD OF COMPARING THE CAPACITIES OF TWO CONDENSERS.

Let B be a battery of constant electromotive force running through the outside resistance $AHDLF$, and let the point D be put to earth. Let C_1 and C_2 be the capacities of the two condensers which we wish to compare, and let one pole of each of these condensers be put to earth. Let the second pole of one of them be touched to H , and the second pole of the other to L for a moment, then let these poles be removed from H and L

FIG. 49.

and connected together by touching them to the ends of the conductor MN . Finally, let the key K be depressed. If, under these circumstances, no current goes through the galvanoscope, the capacities of the condensers are to each other inversely as the resistances R_1 and R_2 of HD and DL .

Conversely, if these resistances are to each other as C_2 to C_1 , no current will go through the galvanoscope.

Take the potential of the earth for a zero, and call the potentials of H and L , V_1 and V_2 , respectively.

Since HD and DL are traversed by the same current,

$$\frac{V_1 - 0}{R_1} = \frac{0 - V_2}{R_2};$$

or,
$$V_2 = -\frac{V_1 R_2}{R_1}.$$

When the poles of the condensers are put in contact with H and L , the first condenser, one of whose poles is to earth and the other at potential V_1 , receives $C_1 V_1$ units of positive electricity from H ; while the other condenser receives $C_2 V_2$ units of positive electricity from L . When the poles of the condensers are removed from H and L , and connected with M and N , we have a compound condenser, of whose poles one is at potential zero, and the other, since the whole charge* is $C_1 V_1 + C_2 V_2$, at potential

$$\frac{C_1 V_1 + C_2 V_2}{C_1 + C_2} = \frac{V_1 (C_1 R_1 - C_2 R_2)}{R_1 (C_1 + C_2)}.$$

If this quantity is zero, that is, if $C_1 : C_2 = R_2 : R_1$, no current will flow through the galvanoscope when the key K is depressed.

73. Properties of the Potential Function inside Conductors which carry Steady Currents. If the value of the potential function within a conductor which bears a steady current is given, all the circumstances of the flow *within* the conductor are fixed. Positive electricity flows into the conductor from without through all parts of the surface where the derivative of the potential function, taken in the direction of the exterior normal, is positive, and out of it through all parts of the surface where this derivative is negative. At all points where the conductor abuts on an insulating medium, the derivative is zero; it may be

* See Equation 188.

zero at other points also. Since there is no free electricity inside a conductor which carries what we have called a steady current, such a current, to use the language of the "Two Fluid Theory," must consist of a flow of positive electricity in one direction at every point, and an equal flow of negative electricity in the opposite direction. There can be no closed equipotential surface lying wholly inside a conductor which carries a steady current, unless there is some constant source of positive or of negative electricity within this surface, for the whole flow of positive electricity per unit of time through such a surface from within outwards is equal to k times the surface integral of the intensity of the component of force in the direction of the exterior normal, and this integral, which cannot vanish, is equal [Section 31] to 4π times the quantity of free electricity within the surface. There must then be such a constant source of free electricity within the surface as shall furnish just as much per unit of time as the current carries away.

It is easy to prove analytically that — given a homogeneous conductor and certain portions, A, B, C, \dots , of its surface which are to be kept at potentials V_A, V_B, V_C, \dots , while at all other portions the value of the derivative of the potential function taken in the direction of the exterior normal is to be zero — there exists a function which (1) satisfies these surface conditions, provided that they do not require at any point of the surface a discontinuity in the potential function or in its derivatives; and which (2) inside the conductor satisfies Laplace's Equation, and with its first space derivatives is finite, continuous, and single valued.

That one such function exists, namely, the potential function inside the conductor when A, B, C , etc., are kept at the given potentials and the rest of the surface is exposed to an insulating medium, is, however, clear enough from physical considerations, but for practical purposes we need to prove that this is the only function which satisfies the given conditions. Suppose for the sake of argument that two such functions, V and W , exist, and call their difference U . The function U , then, satisfies con-

dition (2) and is itself equal to zero, or else has its derivative in the direction of the exterior normal equal to zero at every point of the surface. Applying Green's Theorem in the form of Equation 151 to u , we find that the quantity

$$(D_x u)^2 + (D_y u)^2 + (D_z u)^2,$$

which can never be negative, must be zero at every point within the conductor, so that $D_x u$, $D_y u$, and $D_z u$ must vanish and u be a constant throughout the space within the surface. Now at portions of the surface itself, u is zero, hence it must be equal to zero everywhere inside the conductor, and $V = W$. If by any means, then, we find a function which satisfies the surface conditions and the general space conditions which the potential function inside a certain conductor which bears a steady current under given surface conditions must satisfy, this function is itself the potential function.

Since the sum of any two special solutions of Laplace's Equation is itself a solution of the equation, it is evident that the sum of the potential functions inside a conductor which bears steady currents under two distinct sets of surface conditions, will be the potential function within the same conductor due to the set of surface conditions formed by adding the values of the potential function at the surface in the two original cases. In other words, if we superpose two states of electrokinematic equilibrium in a conductor, the result will be another such state.

Any surface supposed drawn in a conductor which carries a steady current in such a way that the derivative of the potential function taken normal to this surface is zero shall be called a *surface of flow*.

If a conductor which under given surface conditions carries a steady current be cut in two by means of a surface of flow, and if the two parts be separated while the surface conditions on what was the bounding surface of the old conductor remain the same as before, and the fresh surfaces now abut on an insulating medium, the state of flow at every point inside each part of the conductor will be just the same as before, for the

values of V and $D_n V$ on the surface of the new conductors are what they were before separation so that V must have the same values* at all inside points.

When a conductor is cut in two by a surface of flow, the fresh surfaces exposed receive a statical charge of free electricity, and the charges on what was the bounding surface of the original conductor are in part changed so that it is only *within* the parts of the old conductor that the effect of the separation is nil.

74. Method of Finding Cases of Electrokinematical Equilibrium. Although the circumstances of flow within a given conductor are fixed when the value of the potential function within it is known, yet, given a single-valued solution of Laplace's Equation, in general finite and continuous, there is an infinite number of different conductors, all belonging to a certain class, in which the flow is determined by the one function.

For instance, $V = \frac{c}{r} + d$, where c and d are constants and r the distance from a fixed origin O to the point (x, y, z) , gives the value of the potential function inside a conductor bounded by two spherical surfaces of radii a and b having O as their common centre when these surfaces are kept respectively at potentials $\frac{c}{a} + d$ and $\frac{c}{b} + d$. In this case the whole amount, per unit of time, of positive electricity which enters the conductor through the surface $r = a$, crosses every equipotential spherical surface within the conductor, and leaves it by the surface $r = b$ is $4\pi ck$, where k is the specific conductivity of the material out of which the conductor is made. The resistance of the conductor is, by definition,

$$\frac{\frac{c}{a} - \frac{c}{b}}{4\pi ck} = \frac{b - a}{4\pi kab},$$

a quantity independent of c and d .

* See Equation 151.

It is evident that any conical surface whose vertex is O will be in this case a surface of flow, and that the formula $V = \frac{c}{r} + d$ will give us the flow in any piece cut out of the spherical shell just considered by such a surface. It is easy to see that if ω is the solid angle of the cone, the resistance of the portion of the conductor cut out will be $\frac{b-a}{k\omega ab}$.

Again, the equation $V = c\left(\frac{1}{r_1} - \frac{1}{r_2}\right) + d$, where r_1 and r_2 are the distances of the point (x, y, z) from the fixed points O_1 and O_2 , gives us the potential function inside an infinite conductor bounded in part by the surfaces $\frac{1}{r_1} - \frac{1}{r_2} = a$ and $\frac{1}{r_1} - \frac{1}{r_2} = b$, when the first is kept at potential $ac + d$, the second at potential $bc + d$. In this case the surface $V = d$ is a plane bisecting at right angles the straight line O_1O_2 . Larger and smaller values of V than this give closed surfaces, each of which surrounds one of the points and leaves the other outside. For very large values of V , if C is positive, the equipotential surfaces are very small nearly spherical surfaces surrounding O_1 .

To find the amount of positive electricity which enters the conductor under consideration, per unit of time, through the surface $V = ac + d$, where ac shall be positive, we must integrate over this surface $-kD_n V$ or $-kc\left[D_n\left(\frac{1}{r_1}\right) - D_n\frac{1}{r_2}\right]$. According to Gauss's Theorem the resulting integral is exactly the same as that taken over any other closed surface, large or small, which surrounds O_1 and leaves O_2 outside. Let us consider, then, a spherical surface of radius $\epsilon < O_1O_2$ whose centre is at O_1 . The required integral in this case is $-4\pi\epsilon^2k$ times the average value of $D_{r_1}V$ taken over the spherical surface; or, since r_1 for all points on this surface is equal to ϵ ,

$$4\pi\epsilon^2kc\left[\frac{1}{\epsilon^2} + \text{average value of } D_{r_1}\left(\frac{1}{r_2}\right)\right].$$

If now ϵ be made smaller and smaller, $D_{r_1}\left(\frac{1}{r_2}\right)$ always has some finite value for every point on the surface of the sphere surrounding O_1 , and the expression just given approaches the limiting form $4\pi kc$. Hence, $4\pi kc$ units of positive electricity enter the given conductor through the surface $V = ac + d$ in every second, whether this surface is large or small. The resistance of the conductor between the surfaces $V = ac + d$ and $V = bc + d$ is, by definition of the term, $\frac{a-b}{4\pi k}$.

If a and b are made very large and equal, with opposite signs, the two surfaces through which electricity enters and leaves the conductor become very nearly coincident with spherical surfaces of radius $\epsilon = \frac{1}{\alpha}$ drawn about O_1 and O_2 respectively. The resistance of the conductor in this case is $\frac{1}{2\pi k\epsilon}$. Considerations of symmetry show that any plane which contains the line O_1O_2 is a surface of flow. If we cut the conductor in two by such a plane we shall have an infinite conductor with two nearly hemispherical electrodes sunk in its plane surface. The resistance of this part of the whole conductor is $\frac{1}{\pi k\epsilon}$, a quantity independent of the distance apart of the electrodes. This is nearly the case of two poles of a battery sunk in the earth.

Again, the expression

$$V = c \log \frac{r_1}{r_2} + d,$$

where r_1 and r_2 are the distances of a point P in space from any two parallel straight lines, A and B , is a solution of Laplace's Equation which, with its derivatives, vanishes at an infinite distance from these lines and which is constant all over any one of a double system of circular cylindrical surfaces (Fig. 50), some of which surround one of the given lines, and some the other. This function, then, when c and d are properly determined, is the potential function within an infinite lamina,

either thick or thin, when that lamina is perforated perpendicularly to its plane by two circular cylindrical holes, the curved surfaces of which are kept at given constant potentials. $2\pi kc$ units of positive electricity per unit of time per unit of thickness of the lamina enter the conductor through one of the cylindrical surfaces, and the same amount leaves it by the other surface. The resistance of the lamina is then the difference between the values of the potential function at the electrodes divided by $2\pi kc$ times the thickness of the lamina.

FIG. 50.

These examples will serve to show how we may discover an indefinite number of cases of kinematic equilibrium by assuming some function, in general finite and continuous, which satisfies Laplace's Equation, and then taking as a conductor one inside which the given function is everywhere finite, and which is bounded by surfaces over each of which either the function is constant or its normal derivative zero,

EXAMPLES.

1. Show that in general the surface density of a charge distributed on a conductor is greatest at points where the convex curvature of the surface of the conductor is greatest.

2. A hollow in a conductor is at the uniform potential V_1 when a charge is communicated to a conductor within the cavity sufficient to raise this conductor to potential V_2 if it were in empty space. Give some idea of the changes brought about by this charge.

3. Illustrate by a figure the effect on the lines of force of introducing a spherical conductor into any field of force.

4. Prove that if a distribution of electricity over a closed surface produce a force at every point of the surface perpendicular to it, this distribution will produce a potential function constant within the surface.

5. Two conducting spheres of radii 6 and 8 respectively are connected by a long fine wire, and are supposed not to be exposed to each other's influences. If a charge of 70 units of electricity be given to the composite conductor, show that 30 units will go to charge the smaller sphere and 40 units to the larger sphere, if we neglect the capacity of the wire. Show also that the tension in the case of the smaller sphere is $\frac{25}{288\pi} = 2$ per square unit of surface.

6. An uncharged sphere A , of radius r , occupies the centre of the otherwise empty, equipotential cavity, enclosed by a spherical shell B of radii r_1 and r_2 , so large that the effect inside the cavity of the charge induced on B by a charge m , communicated to A from without, may be neglected. If the value of the potential function within the cavity before A was charged was C , at what potential is A now? Ans. $C + \frac{m}{r}$.

7. The first of three conducting spheres, A , B , and C , of radii 3, 2, and 1 respectively, remote from one another, is charged to potential 9. If A be connected with B for an

instant, by means of a fine wire, and if then B be connected with C in the same way, C 's charge will be $3 \cdot 6$. [Stone.] If, in the last example, all three conductors be connected at the same time, C 's charge will be $4 \cdot 5$.

8. A charge of M units of electricity is communicated to a composite conductor made up of two widely separated ellipsoidal conductors, of semiaxes 2, 3, 4 and 4, 6, 8 respectively, connected by a fine wire. Show that the charges on the two ellipsoids will be $\frac{1}{3}M$ and $\frac{2}{3}M$ respectively. [Stone.]

9. Can two electrified bodies repel each other when no lines of force can be drawn from one body to the other?

10. Two conductors, A and B , connected with the earth are exposed to the inductive action of a third charged body. Do A and B act upon each other? If so, how?

11. Show that two equal conductors similarly placed with respect to each other always repel each other if raised to the same potentials and insulated; but that if the values of the potential function within the conductors differ never so little from each other, the conductors will repel each other at great distances, but at very near distances (supposing no spark to pass) they will attract each other. [Cumming.]

12. The superficial density has the same sign at all points of a conducting surface outside which there is no free electricity.

13. Show that $r \div \delta$ of the unit tubes of force proceeding from an electrified particle, at a distance δ from the centre of a conducting sphere of radius r , which is put to earth, meet the sphere if there are no other conductors in the neighborhood, and that the rest go off to "infinity."

14. A charged insulated conductor A is so surrounded by a number of separate conductors B, C, D, \dots , which are put to earth, that no straight line can be drawn from any point of A to the walls of the room without encountering one of these other conductors: will there be any induced charge on the walls of the room? See Section 37.

15. Two uniform straight wires of equal density, each two

inches long, lie separated by an interval of one inch in the same straight line. Find the equation of the equipotential surfaces due to these wires, and find what must be the density of a superficial distribution of matter on one of these surfaces which at all outside points would exert the same attraction as the wires do.

16. An insulated conducting sphere of radius r charged with m units of positive electricity is influenced by m units of positive electricity concentrated at a point $2r$ distant from the centre of the sphere. Give approximately the general shape of the equipotential surfaces in the neighborhood of the sphere.

Give an instance of a positively electrified body whose potential is negative.

17. A conductor, the equation of whose surface is

$$\frac{x^2}{25} + \frac{y^2}{16} + \frac{z^2}{9} = 1,$$

is charged with 80 units of electricity; what is the density at a point for which $x = 3$, $y = 3$?

If the density at this point be α , what is the whole charge on the ellipsoid?

18. Prove that the capacity of n equal spherical condensers when arranged in cascade is only about $\frac{1}{n}$ th of the capacity of one of the condensers; but that if the inner spheres of all the condensers be connected together by fine wires, and the outer conductors be also connected together, the capacity of the complex condenser thus found is about n times that of a single one of the condensers.

19. Prove that if the charges of a system of conductors be increased, the increment of the energy of the system is equal to half the sum of the products formed by multiplying the increase in the charge of each conductor by the sum of the values of the potential function within it at the beginning and the end of the process; or to half the sum of the products formed by multiplying the increment of the value of the potential function

in each conductor by the sum of the original and final charges on that conductor. [Maxwell.]

20. Prove that if the charges of a fixed system of conductors be increased, the sum of the products of the original charge and the final potential of each conductor is equal to the sum of the products of the final charge and the original potential. [Maxwell.]

21. Discuss the following passage from Maxwell's *Elementary Treatise on Electricity* :

“ Let it be required to determine the equipotential surfaces due to the electrification of the conductor C placed on an insulating stand. Connect the conductor with one electrode of the electroscope, the other being connected with the earth. Electrify the exploring sphere,* and, carrying it by the insulating handle, bring its centre to a given point. Connect the electrodes for an instant, and then move the sphere in such a path that the indication of the electroscope remains zero. This path will lie on an equipotential surface.”

22. Prove that the coefficients of potential (p) and induction (q) treated in Article 59 have the following properties :

(1) The order of the suffixes of any p or any q can be inverted without altering the value of the coefficient, or, in other words,

$$p_{kl} = p_{lk} \text{ and } q_{kl} = q_{lk}.$$

(2) All the p 's are positive, but p_{ik} is less than either p_{ii} or p_{kk} .

(3) Those q 's whose two suffixes are the same are positive ; the others are negative. That is, q_{kk} and q_{ii} are positive ; but q_{ki} is negative and is, moreover, numerically less than either of the others.

23. Prove that the following theorems (Maxwell's *Elementary Treatise on Electricity*) are contained in the statements of the preceding problem :

(1) In a system of fixed insulated conductors, the potential function in A_k due to a charge communicated to A_i is equal to the potential function in A_i due to an equal charge in A_k .

* A very small conducting sphere fitted with an insulating handle.

(2) In a system of fixed conductors connected, all but one, with the walls of the room, the charge induced on A_k when A_i is raised to a given potential is equal to the charge induced on A_i when A_k is raised to an equal potential.

(3) If in a system of fixed conductors, insulated and originally without charge, a charge be communicated to A_k which raises it to potential unity and A_i to potential n , then if in the same system of conductors a charge unity be communicated to A_i , and A_k be connected with the earth, the charge induced on A_k will be $-n$.

24. A condenser consists of a sphere A of radius 100 surrounded by a concentric shell whose inner radius is 101, and outer radius 150. The shell is put to earth, and the sphere has a charge of 200 units of positive electricity. A sphere B of radius 100 outside the condenser can be connected with the condenser's sphere by means of a fine insulated wire passing through a small hole in the shell. B is connected with A ; the connection is then broken, and B is discharged; the connection is then made and broken as before, and B is again discharged. After this process has been gone through with five times, what is A 's potential? What would it become if the shell were to be removed without touching A ?

25. Suppose the condenser mentioned in the last problem insulated and a charge of 100 units of positive electricity given to the shell. What will be the potential of the sphere? of the shell? If we then connect the sphere with the earth by a fine insulated wire passing through the shell, what will the charge on the shell be? What will be the potential of the shell? If next A be insulated, and the shell be put to earth, what will be A 's potential? What will be its potential if the shell be now wholly removed?

26. A spherical conductor of radius r is surrounded by a concentric conducting spherical shell of radii R_1 and R_0 , and the outer surface of this shell is put to earth. If the inner conductor be charged, show the effect at all points in space of moving the conductor so that it shall be eccentric with the shell. How is the capacity of the system changed by this?

27. Prove that if the spherical surfaces of radii a and b , which form a spherical condenser, are made slightly eccentric, c being the distance between their centres, the change of electrification at any point of either surface is $\frac{3abc \cdot \cos \theta}{4\pi(b-a)(b^3-a^3)}$,

where θ is the angular distance of the point from the line of centres, and where the difference between the values of the potential function on the two surfaces is unity.

28. Show that if an insulated conducting sphere of radius a be placed in a region of uniform force (X), acting parallel to the axis of x , the function $-X \cdot x \left[1 - \frac{a^3}{r^3} \right] + C$ satisfies all the conditions which the potential function outside the sphere must satisfy, and is therefore itself the potential function. Show that the surface density of the charge on the sphere is $\frac{3xX}{4\pi a}$.

[Watson and Burbury.]

29. Prove that if the negative pole of one cell is connected with the positive pole of another, the two cells form a battery which has the positive pole of the first cell for its positive pole and the negative pole of the second cell for its negative pole. Cells thus connected are said to be joined up "in series" or "tandem." Show that if n equal cells be joined up in series, the battery thus formed will have n times the electromotive force and n times the resistance of one of the single cells. Consider a battery made up of a number of cells not all equal joined up in series.

30. If the positive poles of two equal cells be connected together for a new positive pole, and the negative poles for a new negative pole, the cells are said to be connected in "multiple arc." Show that if n equal cells be joined up in multiple arc, the electromotive force of the battery thus formed is equal to the electromotive force of one of the single cells, but the resistance of the battery is only $\frac{1}{n}$ -th of the resistance of the cell.

Consider a battery made up of n cells not all equal joined up in multiple arc.

31. Show that if the poles of a battery made up of a given number of equal cells are to be connected by a resistance R greater than the sum of the resistance of all the cells, the greatest current will traverse R when the cells are joined up in series, but that if R is very small, the cells should be joined up in multiple arc. If R is such that by arranging the cells in a certain number of parallel rows and joining up the numbers of each row in series the resistance of the whole battery can be made equal to R , this arrangement will give the maximum current.

32. A battery is joined up in simple circuit with a resistance R and a galvanometer of resistance G . After the deflection of the galvanometer has been noted, an additional wire (or shunt) of resistance S is placed across the poles of the battery, and the resistance R is decreased (to r) until the galvanometer deflection is the same as before. Assuming that the electromotive force of the battery remains constant, show that the resistance of the battery is $\frac{S(R-r)}{G+r}$. [Thomson.]

33. How many square centimetres of tin foil must be used in making a parallel plate condenser of one microfarad capacity, if the sheets of foil are to be separated from each other by paraffined paper whose thickness is one-fifth of a millimetre; and whose specific inductive capacity is 2? Ans. $36,000\pi$.

34. Using the potential function $V = c \log r$, where r is the distance from a fixed axis, show that the resistance of a conductor bounded by two concentric circular cylindrical surfaces of radii a and b , and by two planes, distant h from each other, perpendicular to the axis of the cylindrical surfaces, is

$$\frac{\log \left(\frac{b}{a} \right)}{2\pi hk}.$$

Apply the result to the problem of finding the resistance of the liquid in a cylindrical galvanic element.

35. Using the potential function, $V = c \log \frac{r_1}{r_2}$, where r_1 and

r_2 are the distances from two parallel fixed axes, show how to find (see Figure 50) the resistance of a conductor bounded by two parallel planes and by two somewhat eccentric circular cylindrical surfaces which cut the planes orthogonally. In the case of an element in which the zinc electrode is a cylindrical rod and the copper electrode a cylindrical shell surrounding it, is the resistance of the liquid greater or less when the zinc is eccentric to the copper shell than when it is concentric with it?

36. Prove that if at every point of an infinitely long wire, one end of which is kept at potential V_0 , while the potential at the infinitely distant end is zero, there is leakage into the surrounding medium at a rate proportional to the value of the potential function at the point, $V = V_0 e^{-cx}$, where x is the distance from that end of the wire which is kept at potential V_0 .

MISCELLANEOUS PROBLEMS.

1. Prove that the attraction due to a homogeneous hemisphere of radius r is zero, at a point in the axis of the hemisphere distant $\frac{3}{7}r$ approximately from the centre of the base.

2. Show that the attraction at the origin due to the homogeneous solid bounded by the surface obtained by revolving one loop of the curve $r^2 = a^2 \cdot \cos 2\theta$, is $\frac{1}{3} \pi a$.

3. If the earth be considered as a homogeneous sphere of radius r , and if the force of gravity at its surface be g , show that from a point without the earth, at which the attraction is $\frac{n-1}{n}g$, the area $2\pi r^2 \left(1 - \sqrt{\frac{n-1}{n}}\right)$ on the surface of the earth will be visible.

4. A spherical conductor A , of radius a , charged with M units of electricity, is surrounded by n conducting spherical shells concentric with it. Each shell is of thickness a , and is separated from its neighbors by empty spaces of thickness a . Show that the limit approached by V_A as n is made larger and

larger is $\frac{M}{a}$ (nat. log 2), and that for a finite number of shells

$$V_A = \frac{M}{a} \int_0^1 \frac{1 + x^{2n+1}}{1+x} dx. \quad [\text{Stone.}]$$

5. If two systems of matter (M and M'), both shut in by a closed surface S , give rise to potential functions (V and V'), which have equal values at every point of S , whether or not S is an equipotential surface of either system, then V cannot differ from V' at any point outside S , and the algebraic sum of the matter of either system is equal to that of the other. [See Section 52, and Watson and Burbury's *Mathematical Theory of Electricity and Magnetism*, § 60.]

6. Show that if two distributions of matter have in common an equipotential surface which surrounds them both, all their equipotential surfaces outside this will be common.

7. Prove that if V be the potential function due to any distribution of matter over a closed surface S , and if σ' be the density of a superficial distribution on S , which gives rise to the same value of the potential function at each point of S as that of a unit of matter concentrated at any given point O , then the value at O of the potential function due to the first distribution is $\int V' \cdot \sigma \cdot dS$.

8. Show that if we have matter every particle of which attracts every other particle with a force proportional to the n th power of the distance, the attraction at any point within a quantity of the matter will be infinite if $n + 2 < 0$. [Minchin.]

9. Show that if u , v , and w are any three solutions of Laplace's Equation,

$$\nabla^2(uvw) = u \cdot \nabla^2(vw) + v \cdot \nabla^2(uw) + w \cdot \nabla^2(uv).$$

10. Prove that if there be two homogeneous solids of equal density bounded by similar surfaces, their attraction intensities, for the law of the inverse square, at two points similarly situated with respect to them, are in the ratio of the corresponding linear dimensions of the solids. [Newton.]

11. Hence show that the attraction at a point on a given

diameter inside a solid homogeneous ellipsoid varies as the distance of the point from the centre. [Minchin.]

12. Supposing that a sphere of water is brought together by the mutual attractions of its particles from a state of infinite diffusion and that the amount of work done by these forces is sufficient to raise the temperature of the sphere one degree Centigrade; show that the radius of the sphere is about one-fortieth of the radius of the earth, if the earth's radius be 637×10^6 centimetres, and if one water-gramme-centigrade-degree be equivalent to 4.2×10^7 ergs. [Minchin.]

13. We have seen (Section 27) that the amount of work required to move any mass M' in the presence of another mass M from a position L to a position K in any manner is the difference between the values of the potential of M' in the positions K and L . Professor Alfred M. Mayer of the Stevens Institute of Technology has given* for certain cases a graphical illustration of this fact in the shape of a diagram very like those drawn by an indicator attached to a steam-engine.

Let O be the centre of a spherical mass M of repelling matter, and let another spherical mass M' of similar matter be moved up towards O , along the straight line XO , from an infinite distance. At every point of M' 's path suppose an ordinate drawn equal in length to the intensity at that point of the force of repulsion between M and M' , and draw the curve determined by the ends of these ordinates. If, now, K and L are any two points on OX , the area $KLL'K'$, shut in by the curve, the axis of x , and the ordinates at L and K , is numerically equal to the work done in moving M' from L to K , and the whole amount of work done in moving M' from infinity to the

* Professor Mayer, in his paper entitled "Potential as Measured by Work: a Mathematical Discussion," read before the American National Academy on May 10, 1887, supposes the curve mechanically generated by the end of a rod which slides vertically out of the top of M' , in such a way that the distance of the top of the rod from the centre of M' is always numerically equal "to the pressure exerted on M' by the interaction of M' and M ."

position L is the limit approached by the area $LPP'L'$ as P is made to recede indefinitely from O . Prove that this is true, and show by actual computation of the quantities involved that the value of the potential of M' when its centre is at L , is numerically equal to so much of the infinitely extended area between the curve $y = \frac{MM'}{x^2}$ and the axis of x , as lies to the right of the ordinate drawn at L .

FIG. 51.

14. Prove that in general, if M and M' are any two rigid distributions of attracting or repelling matter, and if M' be moved without rotation from one position to another so that a point Q fixed in M' traces out the straight line LK , and if at every point of this line an ordinate be drawn equal in length to the intensity, when Q is at that point, of the component parallel to KL of the force between M and M' , the area bounded by the curve, the axis of x , and the ordinates at K and L will be numerically equal to the work done in moving M' from the one position to the other. Can a similar construction be made when M' moves in any manner from any one position to any other?

15. Assuming the length of the earth-quadrant to be 10,000,000 metres, and the density of the earth to be 5.6, show that the dyne is equivalent to about 15,220,000 centimetre-gramme-second attraction units; so that two masses of about 3901

grammes each, if concentrated at two points a centimetre apart, would attract each other with a force of one dyne.

16. Prove that the intensity at the middle point of its base of the attraction due to a uniform right cone of height h and semi-vertical-angle α is

$$2\pi\rho h \sin\alpha \left\{ \sin\alpha + \cos\alpha - \sin\alpha \cos\alpha \left[1 + \log \operatorname{ctn} \frac{\alpha}{2} \cdot \operatorname{ctn} \left(\frac{\pi}{4} - \frac{\alpha}{2} \right) \right] \right\}.$$

[Minchin.]

17. If the law of attraction is expressed by any function, $\phi'(r)$, of the distance, the intensity of the attraction of any homogeneous solid, estimated in a given direction, at any point P , is expressed by the surface integral $\int \phi(r) \cdot \cos\lambda \cdot ds$, where r is the distance from P of any point on the surface bounding the solid, ds the element of this surface, and λ the angle made by the normal to the element with the given direction. [Minchin.]

18. Prove that if we have matter attracted to any number of fixed centres with forces proportional to any function of the distance, or if we have matter every particle of which attracts every other particle according to any function of the distance between the particles, there exists a "potential function" the derivative of which in any direction at any point gives the intensity of the force which would solicit a unit quantity of matter concentrated at the point to move in the given direction. Is the Newtonian law of attraction the only one which yields a potential function which satisfies Laplace's Equation? Can all these potential functions be used as measures of work?

19. Prove that if any set of operations be performed upon the complex variable $z = x + yi$ taken as a whole, and if the result [$w = f(z)$] be written in the form $\phi(x, y) + i \cdot \psi(x, y)$, where ϕ and ψ , which are said to be conjugate to each other, are real functions of x and y :

(1) Both ϕ and ψ satisfy Laplace's Equation.*

* See Byerly's *Integral Calculus*, Holzmüller's *Isogonale Verwandtschaften*, Minchin's *Uniplanar Kinematics*, Maxwell's *Treatise on Electricity and Magnetism*, Lamb's *Treatise on Fluid Motion*, etc., etc.

(2) $D_x\phi = D_y\psi$ and $D_y\phi = -D_x\psi$.

(3) At any point Q , the derivative of ϕ taken in any direction PQ in the plane xy is equal to the derivative of ψ taken in a direction PR at right angles to PQ , and such that the angle QPR corresponds to a counter-clockwise rotation.

(4) The equations $\phi(x, y) = c$, $\psi(x, y) = c'$, represent two families of curves which cut each other orthogonally.

20. Prove that:

(1) If ϕ and ψ are any two conjugate functions of x and y , that is, if $\phi + i\psi$ is a function of the complex variable $x + yi$, taken as a whole, then, conversely, x and y are two conjugate functions of ϕ and ψ .

(2) If ϕ and ψ are any two conjugate functions of x and y , and if α and β are any two other conjugate functions of x and y , and if for x and y in the expressions for ϕ and ψ we substitute the expressions for α and β , we shall get two new conjugate functions of x and y .

(3) If ϕ_1 and ψ_1 , ϕ_2 and ψ_2 are any two pairs of conjugate functions, $\phi_1 \pm \phi_2$ and $\psi_1 \pm \psi_2$ are conjugate functions of x and y .

21. Prove that in any case of steady uniplanar flow of electricity, — that is, flow which at every point is parallel to a given plane, and of such a character that its intensity and direction is the same at all the points of any line drawn perpendicular to the given plane, — there exists a function conjugate to the potential function. This function is called the “flow function.”

22. Show by the ordinary rules for treating imaginary quantities that, if $z = x + yi$, z^2 , \sqrt{z} , $\log z$ will yield respectively the following pairs of conjugate functions: $A(x^2 - y^2)$; $-2Axy$; $Ar^{\frac{1}{2}} \cos \frac{\theta}{2}$, $Ar^{\frac{1}{2}} \sin \frac{\theta}{2}$; $A \log r$, $A\theta$; where $r^2 = x^2 + y^2$ and

$\theta = \tan^{-1} \frac{y}{x}$. State some problems of steady flow within conductors which these conjugate functions will help to solve.

23. Show that, with certain broad limitations, either one (say ϕ) of any pair $[\phi, \psi]$ of conjugate functions of x and y may be taken as the potential function in empty space due to

an electrostatic distribution the density of which is a function of x and y only, and which, therefore, must be constant at all points on any indefinitely extended line drawn perpendicular to the plane of xy . Show also that in the case of the same distribution the other function ψ will be constant along any line of force.

24. Show that either one (say ϕ) of any pair $[\phi, \psi]$ of conjugate functions of x and y may be taken as the potential function inside a conductor which carries a steady current flowing at every point in a direction parallel to the plane of xy and the same in intensity and direction at all points of any line drawn perpendicular to this plane. Show that in this case the other function ψ will be constant along any line of flow, and that the two equations $\phi = c$, $\psi = c'$ represent, respectively, if c and c' are parameters, cylindrical equipotential surfaces and cylindrical surfaces of flow. If ds is the element of any curve AB in the plane xy , and if $D_n\phi$ is the derivative of ϕ taken in the direction of the normal to ds which points towards the right as one goes along the curve from A to B , the integral $-k \int_A^B D_n\phi \cdot ds$ gives the amount of positive electricity which crosses per unit of time from left to right so much of a right cylindrical surface erected on AB as is enclosed by two planes parallel to the plane of xy and at the unit distance from each other. Since $D_n\phi = D_n\psi$, the integral just considered is equal to $-k(\psi_B - \psi_A)$, and $-k$ times the difference between the values of ψ on two right cylindrical surfaces of flow gives the amount of flow across the unit height of so much of any cylindrical surface which cuts the plane of xy at right angles as is included between the given surfaces of flow.

25. Prove that:

(1) If $r_1, r_2, r_3, \dots, r_n$ are the lengths of the radii vectores drawn from any point P to any n parallel axes, and if $\theta_1, \theta_2, \theta_3, \dots, \theta_n$ are the angles which these radii vectores make with a fixed line in the plane of xy which is perpendicular to the axes,

$$\phi = A_1 \log r_1 + A_2 \log r_2 + A_3 \log r_3 + \dots + A_n \log r_n,$$

$$\psi = A_1 \theta_1 + A_2 \theta_2 + A_3 \theta_3 + \dots + A_n \theta_n,$$

are conjugate solutions of Laplace's Equation.

(2) The equation $\psi = c'$ represents for each value of c' a cylindrical surface which passes through all the axes.

(3) For very large values of c , the equation $\phi = c$ represents, at least in part, as many closed cylindrical surfaces, each surrounding one of the axes, as there are positive terms in the expression for ϕ .

(4) For very large negative values of c , the equation $\phi = c$ represents, at least in part, so many closed cylindrical surfaces, each surrounding one of the axes, as there are negative terms in ϕ .

(5) If $\sum A = 0$, no one of the cylindrical surfaces $\psi = c'$ ends at infinity.

(6) The value of $\int D_n \phi ds$ taken around any closed curve in the plane xy which surrounds the j th axis and no other is equal to the change made in ψ by going around the curve [see Example 24], and this is $2\pi A_j$.

(7) However the axis may be distributed and whatever values may be assigned to the A 's, ϕ represents the potential function corresponding to a uniplanar flow of electricity* within the substance of an infinite conducting lamina, either thick or thin, when cylindrical holes, on the curved surface of each one of which ϕ is constant, are cut through the lamina so as to remove all the axes, and if the curved surfaces of these holes are kept at potentials equal to the values of ϕ on them. This is practically the case of a very large thin sheet of metal touched at certain points by the ends of wires connected with the poles of batteries.

(8) If in the value of ϕ there is an even number ($2m$) of terms, half of which are positive and half negative, and if,

* See papers by Foster and Lodge in the *Philosophical Magazine* for 1875 and 1876.

moreover, all the A 's are numerically equal, we have the case in which m equal pieces of wire connected with the positive pole of a battery touch a thin sheet of metal in m places, and m similar pieces of wire connected with the negative pole of the battery touch the metallic sheet in m other places. In this case, if P_1 and P_2 are any two points in the metal, the resistance of so much of the sheet as lies between the equipotential surfaces on which P_1 and P_2 lie, is $\frac{\phi_{P_2} - \phi_{P_1}}{2\pi Ank\delta}$, when δ is the thickness of the lamina, and k its specific conductivity.

(9) If ϕ consists of two terms the coefficients of which are numerically equal but opposite in sign, we have the case of a thin sheet of metal touched at two points by the two poles of a battery. Here the curves in the plane xy , for which ψ is constant, are circles (Fig. 50) whose centres are on the line which bisects at right angles the line which gives the points where the battery electrodes touch the sheet.

Show that this value of ϕ enables us to find the resistance of a thin circular disc touched at two points on its circumference by the poles of a battery, and hence, by superposition, the resistance of such a disc touched by any number of pairs of battery poles at different places on the circumference. State other problems which an inspection of Figure 50 shows can be solved by the aid of the value of ϕ .

(10) If ϕ is made up of an infinite number of terms with coefficients all numerically equal, but alternately positive and negative, and if the corresponding axes cut the plane of xy in a straight line so that the distance between any axis and the next is b , certain of the lines of force in the plane of xy will be straight lines which cut at right angles the line on which the traces of the axes lie. Show that by aid of this ϕ we can find the resistance of a lamina of breadth b , and of infinite length when touched at two points opposite each other, one on one edge, and the other on the other. Draw from general knowledge a diagram which shall give the shape of the lines of flow and the equipotential lines in such a lamina.

26. Prove that where there is symmetry about the axis from which θ is measured, $r^m \cdot P_m(\cos \theta)$ and $\frac{P_m(\cos \theta)}{r^{m+1}}$, where $P_m(\cos \theta)$ is the coefficient of α^m in the development, in ascending powers of α , of $(1 - 2\alpha \cos \theta + \alpha^2)^{-\frac{1}{2}}$, are particular solutions of Laplace's Equation in polar coördinates; that is, of

$$r \cdot D_r^2(rV) + \frac{1}{\sin \theta} \cdot D_\theta(\sin \theta \cdot D_\theta V) = 0.$$

27. Hence show that any expression of the form

$$A_0 + A_1 r \cdot P_1(\cos \theta) + A_2 r^2 \cdot P_2(\cos \theta) + \dots + A_n \cdot r^n P_n(\cos \theta) \\ + \frac{B_0}{r} + \frac{B_1 \cdot P_1(\cos \theta)}{r^2} + \frac{B_2 \cdot P_2(\cos \theta)}{r^3} + \dots + \frac{B_m \cdot P_m(\cos \theta)}{r^{m+1}},$$

where $A_0, B_0, A_1, B_1, A_2, B_2$, etc., are arbitrary constants, satisfies the equation. The P 's here introduced are sometimes called Legendre's Coefficients, sometimes Zonal Surface Spherical Harmonics.

28. Show that $P_0(\mu) = 1$,

$$P_1(\mu) = \mu,$$

$$P_2(\mu) = \frac{1}{2}(3\mu^2 - 1),$$

$$P_3(\mu) = \frac{1}{2}(5\mu^3 - 3\mu),$$

$$P_4(\mu) = \frac{1}{8}(35\mu^4 - 30\mu^2 + 3),$$

$$P_5(\mu) = \frac{1}{8}(63\mu^5 - 70\mu^3 + 15\mu).$$

29. Show that when $\theta = 0$, $P_m(\cos \theta)$, or $P_m(1)$, the coefficient of α^m in the development of $(1 - \alpha)^{-1}$, is equal to 1.

30. Prove that, if in any case of symmetry about a line, a convergent series $a_0 + a_1 z + a_2 z^2 + a_3 z^3 + \dots$ represents the value of the potential function at a point Q distant z from the fixed point O , both O and Q being on the line, then the series

$$a_0 P_0(\cos \theta) + a_1 r P_1(\cos \theta) + a_2 r^2 P_2(\cos \theta) + a_3 r^3 P_3(\cos \theta) + \dots$$

formed by writing instead of z^m in the former series $r^m \cdot P_m(\cos \theta)$, will represent in polar coördinates with O as origin and the given line as axis from which θ is measured, a finite, single-valued function which satisfies Laplace's Equation and for all points on the given line on the positive side of O , where $\theta = 0$

and $r = z$, has the same values as the given series. Given the radius of convergence of the first series, within what limits can we safely use the second series? If any portion of the given line traverses a region of empty space, does the new series represent the potential function at all points in this region within the limits of convergency of the series?

31. Prove that if in any case of symmetry about a line, a convergent series $\frac{a_1}{z} + \frac{a_2}{z^2} + \frac{a_3}{z^3} + \dots$ represents the value of the potential function, the series

$$\frac{a_1 P_0(\cos \theta)}{r} + \frac{a_2 P_1(\cos \theta)}{r^2} + \frac{a_3 P_2(\cos \theta)}{r^3} + \dots$$

formed by writing instead of $\frac{1}{z^{m+1}}$ in the former series $\frac{P_m(\cos \theta)}{r^{m+1}}$, will represent, so long as the new series is convergent, a finite, single-valued function which satisfies Laplace's Equation and, for all points on the line on the positive side of O , has the same values as the given series.

32. Prove that the potential function due to a uniform circular ring of mass M , of radius a , and of small cross-section is equal to

$$\frac{M}{r} \left(1 - \frac{1}{2} \cdot \frac{a^2 \cdot P_2(\cos \theta)}{r^2} + \frac{1 \cdot 3}{2 \cdot 4} \cdot \frac{a^4 \cdot P_4(\cos \theta)}{r^4} - \dots \right),$$

if $a < r$, and to

$$\frac{M}{a} \left(1 - \frac{1}{2} \frac{r^2 \cdot P_2(\cos \theta)}{a^2} + \frac{1 \cdot 3}{2 \cdot 4} \cdot \frac{r^4 \cdot P_4(\cos \theta)}{a^4} - \dots \right),$$

if $a > r$, where the centre of the ring is the origin, and the axis of the ring the axis from which θ is measured.

33. Prove that the potential function due to a uniform circular disc of mass M , of radius a , and of small thickness, is equal to

$$\frac{2M}{a^2} \left(\frac{1}{2} \cdot \frac{a^2}{r} - \frac{1}{2^2 \cdot 2!} \frac{a^4 \cdot P_2(\cos \theta)}{r^3} + \frac{1 \cdot 3}{2^3 \cdot 3!} \frac{a^6 \cdot P_4(\cos \theta)}{r^5} - \dots \right),$$

if $a < r$, and to

$$\frac{2M}{a^2} \left(a - r \cdot P_1(\cos \theta) + \frac{1}{2} \cdot \frac{r^2 \cdot P_2(\cos \theta)}{a} - \frac{1}{2^2 \cdot 2!} \frac{r^4 \cdot P_4(\cos \theta)}{a^3} + \dots \right),$$

if $a > r$, where the centre of the ring is the origin.

ADDITIONAL ANSWERS TO PROBLEMS.

CHAPTER I.

$$(1) X = \frac{113032}{274625}, Y = \frac{96501}{274625}, \text{ whence } R = 0.541 + ;$$

$$\theta = 40^\circ 29' +.$$

$$(2) R = m\lambda, \cos \alpha = \frac{1}{a^2\lambda}, \cos \beta = \frac{1}{b^2\lambda}, \cos \gamma = \frac{1}{c^2\lambda}, \text{ where}$$

$$\lambda = \sqrt{\frac{1}{a^4} + \frac{1}{b^4} + \frac{1}{c^4}}.$$

(5) If $2l$ be the length of the wire, and if the axis of the wire be taken for the axis of abscissas with the origin at the middle point, the required equation is

$$2c^2x^2 - 1 = \frac{l^2 - x^2 - y^2}{[(l-x)^2 + y^2]^{\frac{1}{2}} \cdot [(l+x)^2 + y^2]^{\frac{1}{2}}}.$$

(6) If the radius of the earth be taken as 3960 miles, and the mass of a cubic foot of water as 62.5, one poundal is equivalent to 952 million attraction units approximately.

(8) If c be the distance of the point P from the centre of the sphere, the required attraction is $m \left[\frac{1}{c^2} - \frac{1}{8(c \pm r)^2} \right]$, if P is without the solid; $\frac{m}{8r^2}$, if P is within the cavity, and

$$\frac{m}{8r^3} \left[c - \frac{r^3}{(c+r)^2} \right],$$

if P is a point in the mass of the solid.

(9) The attraction of a hemisphere of radius R at a point P facing the flat side of the hemisphere and lying on the perpendicular to this side erected at the centre O is

$$\frac{M}{2a^2R^3} [R^3 - 2a^3 + (2a^2 - R^2)\sqrt{R^2 + a^2}], \text{ where } a = OP.$$

The attraction of the other hemisphere may be found by subtracting this quantity from the attraction due to the whole sphere of which this hemisphere is a part. See § 9.

(10) (a) That the density varies inversely as the distance from the centre.

$$(b) \quad \frac{M}{4\pi R^2} \left[\frac{2}{r} + \frac{2R}{981nr} - \frac{1}{327n} \right].$$

$R^{n-2} - (R-r)^{n-2} = \frac{5.6}{2.9}$
 $R = \text{radius in cm.}$
 $n = ?$

(12) Here d is supposed to be greater than a .

(15) The attraction is 34.9, and its line of action makes an angle of $1^\circ 49'$ with the line joining the centre of the sphere with the point in question.

CHAPTER II.

(7) That the force is constant.

$$(9) \quad V_{0-1} = \frac{2}{3}\pi\rho(18 - c^2); \quad V_{1-2} = \frac{2}{3}\pi\rho\left(15 + \frac{2}{c}\right);$$

$$V_{2-3} = \frac{2}{3}\pi\rho\left(27 - \frac{14}{c} - c^2\right); \quad V_{1-\infty} = \frac{2}{3}\pi\rho\frac{40}{c}.$$

(11) Yes; 1.46 - .

$$(12) \quad \text{If } 3 > r, \quad V = \pi\mu\left(\frac{298}{3} - \frac{2r^2}{3}\right);$$

$$\text{if } 4 > r > 3, \quad V = \pi\mu\left(\frac{244}{3} + \frac{36}{r}\right);$$

$$\text{if } 5 > r > 4, \quad V = \pi\mu\left(\frac{500}{3} - \frac{r^3}{3} - \frac{220}{r}\right);$$

$$\text{if } r > 5, \quad V = \pi\mu\frac{405}{r}.$$

(15) No.

(20) (1) About 1,830,000 tons of 2000 pounds each.

CHAPTER V.

(9) Yes.

(14) Yes.

(17) $\sigma = 0.44$, $m = a(1.81 +)$.(24) $\frac{2}{101} \left(\frac{101}{102} \right)^5$; $2 \left(\frac{101}{102} \right)^5$.(25) $\frac{2}{3}$; $\frac{2}{3}$; $\frac{4040}{41}$ on inside of shell, $\frac{60}{41}$ on outside of shell;

A Treatise on Plane Surveying.

By DANIEL CARHART, C.E., Professor of Civil Engineering in the Western University of Pennsylvania, Allegheny. Illustrated. 8vo. Half leather. xvii + 498 pages. Mailing Price, \$2.00; for introduction, \$1.80.

THIS work covers the whole ground of Plane Surveying. It illustrates and describes the instruments employed, their adjustments and uses; it exemplifies the best methods of solving the ordinary problems occurring in practice, and furnishes solutions for many special cases which not infrequently present themselves. It is the result of twenty years' experience in the field and technical schools, and the aim has been to make it extremely practical, having in mind always that to become a *reliable* surveyor the student needs frequently to manipulate the various surveying instruments in the field, to solve many examples in the class-room, and to exercise good judgment in all these operations. Not only, therefore, are the different methods of surveying treated, and directions for using the instruments given, but these are supplemented by various field exercises to be performed, by numerous examples to be wrought, and by many queries to be answered.

Chapter I. **Chain Surveying.**

“ II. **Compass and Transit Surveying.**

“ III. **Declination of the Needle.**

“ IV. **Laying Out and Dividing Land.**

“ V. **Plane Table Surveying.**

“ VI. **Government Surveying.**

“ VII. **City Surveying.** Including the Principles of Levelling.

“ VIII. **Mine Surveying.** Including the Elements of Topography.

The following **Tables** have been added: Logarithms of numbers; Approximate equation of time; Logarithms of trigonometric functions; For determining with greater accuracy than the preceding; Lengths of degrees of latitude and longitude; Miscellaneous formulas, and equivalents of metres, chains, and feet; Traverse; Natural sines and cosines; Natural tangents and cotangents.

The judicial functions of surveyors, as given by Chief Justice Cooley, are set forth in an appendix.

The work is published just as this Catalogue goes to press, so that full notices cannot be given. Send for the special circular.

Byerly's Syllabi.

By W. E. BYERLY, Professor of Mathematics in Harvard University.
Each, 8 or 12 pages, 10 cents.

Elements of the Differential and Integral Calculus.

With Examples and Applications. By J. M. TAYLOR, Professor of Mathematics in Madison University. 8vo. Cloth. 249 pages. Mailing Price, \$1.95; Introduction Price, \$1.80.

THE aim of this treatise is to present simply and concisely the fundamental problems of the Calculus, their solution, and more common applications. Its axiomatic datum is that the change of a variable, when not uniform, may be conceived as becoming uniform at any value of the variable.

It employs the conception of rates, which affords finite differentials, and also the simplest and most natural view of the problem of the Differential Calculus. This problem of *finding the relative rates of change of related variables* is afterwards reduced to that of finding the limit of the ratio of their simultaneous increments; and, in a final chapter, the latter problem is solved by the principles of infinitesimals.

Many theorems are proved both by the method of rates and that of limits, and thus each is made to throw light upon the other. The chapter on differentiation is followed by one on direct integration and its more important applications. Throughout the work there are numerous practical problems in Geometry and Mechanics, which serve to exhibit the power and use of the science, and to excite and keep alive the interest of the student.

The Nation, New York: It has two marked characteristics. In the first place, it is evidently a most carefully written book. There is nothing vague or slipshod in it. Nearly every sentence, certainly every theorem, seems to have been constructed with a strenuous effort to give it clearness and precision. This constant attention to the form of expression has enabled the author to be concise without becoming obscure. We are acquainted with no text-book of the calculus which compresses so much matter into so few pages, and at the same time leaves the impression that all that is necessary has been said. In the second place, the number of carefully selected examples, both of those worked out in full in illustration of the text, and of those left for the student to work out for himself, is extraordinary. From this point of view, those teachers and pupils who are accustomed to or prefer a different text-book, would still do well to provide themselves with this, regarding it merely as a collection of examples and without any reference to the text.

Elementary Co-ordinate Geometry.

By W. B. SMITH, Professor of Physics, Missouri State University. 12mo. Cloth. 312 pages. Mailing Price, \$2.15; for introduction, \$2.00.

WHILE in the study of Analytic Geometry either gain of knowledge or culture of mind may be sought, the latter object alone can justify placing it in a college curriculum. Yet the subject may be so pursued as to be of no great educational value. Mere calculation, or the solution of problems by algebraic processes, is a very inferior discipline of reason. Even geometry is not the best discipline. In all thinking, the real difficulty lies in forming clear notions of things. In doing this all the higher faculties are brought into play. It is this formation of concepts, therefore, that is the essential part of mental training. And it is in line with this idea that the present treatise has been composed. Professors of mathematics speak of it as the most exhaustive work on the subject yet issued in America; and in colleges where an easier text-book is required for the regular course, this will be found of great value for post-graduate study.

Wm. G. Peck, Prof. of Mathematics and Astronomy, Columbia College: I have read Dr. Smith's Co-ordinate Geometry from beginning to end with unflagging interest. Its well compacted pages contain an immense amount of matter, most admirably arranged. It is an excellent book, and the author is entitled to the thanks of every lover of mathematical science for this valuable contribution to its literature. I shall recommend its adoption as a text-book in our graduate course.
